A-Level Biology

Name: _____ Score: _____

1. Most features, such as height, are caused by:
 - ☐ both genetic and environmental factors
 - ☐ genetic factors only
 - ☐ environmental factors only
 - ☐ neither genes nor environment
2. Natural selection acts on the variation that already exists in a population.
 - ☐ True ☐ False
3. A change in the allele frequencies of a population over generations is called _____.

4. Selective breeding (artificial selection) differs from natural selection because:
 - ☐ humans choose which organisms breed, rather than nature
 - ☐ no alleles are passed on
 - ☐ it never changes the population
 - ☐ it only happens in bacteria
5. Evolution is best described as:
 - ☐ the gene pool of a population changing over generations, forming new species
 - ☐ an individual changing during its life
 - ☐ the loss of all genetic variation
 - ☐ a single mutation
6. Continuous variation is:
 - ☐ a smooth range controlled by many genes plus the environment
 - ☐ clear separate groups controlled by one gene
 - ☐ caused only by the environment
 - ☐ the same in every individual
7. In natural selection, which individuals are most likely to pass on their alleles?
 - ☐ those best adapted, which survive and reproduce
 - ☐ the largest ones only

☐ a random selection

☐ those that produce the fewest offspring

8. When humans choose which organisms breed to pass on useful features, it is called _____ selection.

9. Speciation is the formation of a new species, when two populations can no longer interbreed.

☐ True ☐ False

10. Repeated artificial selection from a few individuals can reduce the gene pool and cause inbreeding problems.

☐ True ☐ False

A-Level Biology

1. **both genetic and environmental factors**

Height depends on the alleles inherited and on diet/lifestyle — a combination of genes and environment.

2. **True**

It cannot create variation; it selects from what is already there (mutation creates the new variation).

3. **evolution**

Selection and genetic drift change allele frequencies — that is evolution at the genetic level.

4. **humans choose which organisms breed, rather than nature**

In artificial selection, people choose the breeders to pass on useful features; in natural selection, the environment selects.

5. **the gene pool of a population changing over generations, forming new species**

Evolution is the change in a population's gene pool over time, which can lead to new species.

6. **a smooth range controlled by many genes plus the environment**

Continuous variation (e.g. height) is a smooth range from many genes; discontinuous is separate groups from few genes.

7. **those best adapted, which survive and reproduce**

The best-adapted individuals survive, reproduce, and pass on their helpful alleles, which spread over generations.

8. **artificial**

Artificial selection (selective breeding) is the same mechanism as natural selection — but humans, not the environment, do the selecting.

9. **True**

It can be allopatric (geographical barrier) or sympatric (same area).

10. **True**

A narrow gene pool concentrates harmful recessive alleles and lowers the population's resilience.

17.1 Variation

Name: _____ Class: _____ Date: _____

Total: 10 marks

KEY WORDS variation 变异 • genetic 遗传 • continuous 连续 • continuous variation 连续变异 • discontinuous 不连续

Objective

Build the skills to answer exam questions on **variation** — **genetic** 遗传 and **environmental** 环境 causes, **continuous** 连续 and **discontinuous** 不连续 variation, and comparing samples with the **t-test**.

You must be able to:

- explain genetic, environmental and combined causes of phenotypic variation
- explain continuous and discontinuous variation and their genetic basis
- use a t-test to compare the means of two samples

1 Worked examples

■ Causes and patterns of variation

Discontinuous variation falls into separate groups; continuous variation is a smooth range

directional: favors one extreme · stabilising: favors mean · disruptive: favors both extremes

Variation is acted on by the types of selection

- **genetic only** — set by alleles (e.g. blood group); **environmental only** — set by surroundings (e.g. a scar); most features are a **combination** (e.g. height).
- **discontinuous**: separate categories, controlled by one or a few **genes** 基因, little environmental effect.
- **continuous**: a smooth range, controlled by **many genes** plus the environment.

■ The t-test

The **t-test** compares the **means** of two samples to see whether their difference is real or just chance. A large t (beyond the critical value) means the difference is significant; a small t means it could be due to chance.

2 Practice

2.1 State whether each is continuous or discontinuous variation: human height; ABO blood group. [2]

2.2 Give **one** example of a feature caused by both genes and the environment. [1]

3 Exam-style questions

3.1 Which feature shows discontinuous variation? [1]

- **A** body mass
 - **B** ABO blood group
 - **C** height
 - **D** skin colour
-

3.2 Continuous variation is usually caused by: [1]

- **A** a single gene only
 - **B** many genes together, plus the environment
 - **C** the environment only
 - **D** a chromosome mutation
-

3.3 A student measures the heights of plants grown in sun and in shade and wants to know if the difference in mean height is significant.

(a) Name a statistical test the student should use. [1]

(b) The calculated t value is greater than the critical value at $p = 0.05$. State what this tells the student. [2]

3.4 Explain why two genetically identical plants can still differ in height. [2]

Solutions

2.1 height — continuous; ABO blood group — discontinuous.

2.2 e.g. height / body mass / skin colour.

3.1 B. ABO blood group falls into separate categories.

3.2 B. Continuous variation is polygenic and affected by the environment.

3.3 (a) the t-test.

(b) the difference between the means is significant; it is unlikely (less than 5% probability) to be due to chance.

3.4 the environment differs (e.g. light, water, minerals); environmental factors affect the phenotype as well as the genes.

- 2 *Exserohilum turcicum* is a fungal pathogen. The growth of the mycelium of the fungus damages the leaves of maize plants, *Zea mays*. Leaf damage reduces crop yield.
- (a) (i) Complete Table 2.1 to show **one** structural difference and **one** functional difference between *E. turcicum* and *Z. mays*.

Table 2.1

	<i>E. turcicum</i>	<i>Z. mays</i>
structural difference		
functional difference		

[2]

- (ii) Describe the principles by which organisms such as *E. turcicum* and *Z. mays* are classified in the taxonomic hierarchy.

[4]

- (b) Two inbred varieties of maize, SKV50 and CML153, were crossed. The resulting F1 hybrids were self-crossed to produce F2 offspring. The F2 plants were grown, and the percentage area of leaf damage caused by *E. turcicum* was measured.

Fig. 2.1 shows the results for the F2 generation. The arrows show the mean percentage area of leaf damage for the two parent varieties.

Fig. 2.1

- (i) Explain how Fig. 2.1 can be used to determine which parent maize variety shows the greatest resistance to infection by *E. turcicum*.

.....
.....
.....
..... [2]

- (ii) State the name of the type of variation shown by the maize F2 generation in Fig. 2.1.

..... [1]

- (iii) Explain the **genetic** basis of the type of variation shown by the maize F2 generation.

17.2 Natural and artificial selection

Name: _____ Class: _____ Date: _____

Total: 12 marks

KEY WORDS natural selection 自然选择 • selective breeding 选择育种 • genetic drift 遗传漂变 • founder effect 奠基者效应 • hardy–weinberg principle 哈迪

Objective

Build the skills to answer exam questions on **natural and artificial selection** — **natural selection** 自然选择, types of selection, the **founder effect** 奠基者效应 and **genetic drift** 遗传漂变, the **Hardy–Weinberg principle** 哈迪-温伯格原理, and **selective breeding** 选择育种.

You must be able to:

- explain natural selection and how it acts as a stabilising, directional or disruptive force
- explain the founder effect, genetic drift and the bottleneck effect
- use the Hardy–Weinberg principle and describe selective breeding

1 Worked examples

■ Natural selection and its forces

Populations make more offspring than can survive, so they **compete** 竞争; the best **adapted** 适应 survive, reproduce and pass on their alleles, so helpful alleles become more common.

directional: favors one extreme • stabilising: favors mean • disruptive: favors both extremes

Stabilising favours the average; directional favours one extreme; disruptive favours both extremes

■ Changing allele frequencies

A bottleneck (or founder effect) leaves few alleles; genetic drift changes frequencies by chance

Antibiotic resistance is natural selection: a chance mutation makes some bacteria resistant; the antibiotic kills the rest; the resistant survivors reproduce.

■ Hardy–Weinberg

With $p + q = 1$ and $p^2 + 2pq + q^2 = 1$, you can find allele and genotype frequencies (when the population is large, mating random, and there is no mutation, migration or selection).

■ Selective breeding

Humans choose which organisms breed, so useful features (e.g. disease resistance, milk yield) increase

2 Practice

2.1 Name the type of selection that favours the average and removes the extremes. [1]

2.2 State **two** conditions under which the Hardy–Weinberg principle holds. [2]

3 Exam-style questions

3.1 A change that favours one extreme of a range, shifting the mean, is: [1]

- **A** stabilising selection
 - **B** directional selection
 - **C** disruptive selection
 - **D** genetic drift
-

3.2 The bottleneck effect reduces a population's: [1]

- **A** mutation rate
 - **B** genetic variety (allele variety)
 - **C** birth rate
 - **D** number of chromosomes
-

3.3 In a population, the recessive phenotype (genotype q^2) occurs in 16% of individuals.

(a) Calculate the frequency of the recessive allele, q . [2]

(b) Calculate the frequency of heterozygotes ($2pq$). [2]

3.4 Explain how the overuse of antibiotics leads to a resistant bacterial population, using the idea of natural selection. [3]

Solutions

2.1 stabilising selection.

2.2 any two: large population; random mating; no mutation; no migration; no natural selection.

3.1 B. Directional selection shifts the mean towards one extreme.

3.2 B. A bottleneck leaves few survivors, reducing allele variety.

3.3 (a) $q^2 = 0.16$, so $q = \sqrt{0.16} = 0.4$.

(b) $p = 1 - q = 0.6$; $2pq = 2(0.6)(0.4) = 0.48$.

3.4 a chance mutation makes some bacteria resistant; using the antibiotic kills the non-resistant bacteria; the resistant ones survive and reproduce, so the resistant allele becomes more common.

4 The wolf, *Canis lupus*, lives in North America. Wolves may have a grey or a black coat colour. The colour of an individual wolf depends on the DNA it inherits at the *CPD103* gene locus.

- Wolves inherit two copies of *CPD103*, one from each parent.
- Wolves that inherit one copy of the black form of the *CPD103* gene have a black coat.

(a) State the term used to describe:

- an organism that has two copies of each gene
- a form of a gene
- a form of a gene that gives a phenotypic effect in a heterozygote.

[3]

In addition to producing black coat colour, the protein coded for by the *CPD103* gene also defends against infectious lung disease.

Canine distemper virus (CDV) causes serious lung disease in wolves. Wolves that have been previously infected by CDV have antibodies against CDV (anti-CDV antibodies) in their blood.

(b) CDV can be passed from domestic dogs to wolves.

- Domestic dogs are more numerous in the southern part of the area occupied by wolves.
- Domestic dogs are less numerous in the northern part of the area occupied by wolves.
- The relative frequency of black wolves compared to grey wolves increases from the north to the south of the area they occupy.

Explain how natural selection causes this trend in the distribution of black wolves.

.....

.....

.....

.....

.....

.....

.....

.....

.....

..... [4]

(c) Several different populations of wolves were compared.

Fig. 4.1 shows the relationship between the percentage of wolves in a population that have anti-CDV antibodies in their blood and the percentage of wolves in that population that are black. The line of best fit was calculated after comparing the different populations of wolves.

Fig. 4.1

With reference to Fig. 4.1, state the relationship between the percentage of wolves with anti-CDV antibodies and wolf coat colour, **and** suggest reasons for this relationship.

[Total: 11]

4 The evolution of antibiotic resistance in bacteria has occurred as a result of natural selection.

(a) Name **two** ways in which a bacterium can become resistant to an antibiotic.

.....

..... [2]

(b) The World Health Organisation regularly analyses bacterial DNA sequence data.

Suggest **one** way in which this contributes to solving the problem of antibiotic resistance in bacteria.

.....

.....

..... [1]

(c) Some infectious bacterial diseases are treated with the antibiotic streptomycin.

If a person does **not** finish the prescribed course of streptomycin, bacteria are more likely to become resistant to the antibiotic.

Explain why a streptomycin-resistant strain of bacteria is more likely to develop as a result of natural selection when a person does **not** complete the prescribed course of antibiotics.

Question 5 starts on page 12.

5 The Galápagos is a group of islands with a high biodiversity.

- (a) *Geospiza fortis* is one of the many species of finch that live on the Galápagos islands. On one of the Galápagos islands, Daphne Major, scientists measured the bill size (length, width and depth) of individuals in a population of *G. fortis* over several years.

Fig. 5.1 shows a *G. fortis* female.

Fig. 5.1

G. fortis feed on seeds. Seed size and bill size vary. It is easier for *G. fortis* with smaller bills to eat small seeds and for *G. fortis* with larger bills to eat large seeds.

In 1977, a drought occurred on Daphne Major, which resulted in a large decrease in the availability of seeds, particularly small seeds.

Scientists observed an increase in the mean bill size in the *G. fortis* population on Daphne Major after the drought.

- (i) State the type of natural selection that occurred in the *G. fortis* population on Daphne Major as a result of the drought.

..... [1]

- (ii) Fig. 5.2 shows the distribution of bill size in the *G. fortis* population before the drought in 1977.

Fig. 5.2

Sketch a new curve on Fig. 5.2 to show the distribution of bill size in the *G. fortis* population after the drought.

(b) *G. fortis* also lives on Santa Cruz, another island in the Galápagos.

Most of the seeds available for *G. fortis* to eat on Santa Cruz are either small or large. There are few intermediate sizes of seed.

Fig. 5.3 shows the distribution of bill size in the *G. fortis* population on Santa Cruz.

Fig. 5.3

Explain how natural selection in the *G. fortis* population on Santa Cruz has resulted in the distribution in bill size shown in Fig. 5.3.

..... [4]

- (c) Scientists studied the effect of an increase in the number of tourists each year on the number of invasive alien species present in the Galápagos islands.

The scientists recorded the number of invasive alien species present each year in the Galápagos islands over many years. The scientists also recorded the number of tourists visiting the islands each year.

Fig. 5.4 shows a graph of the data for five different years during the study.

Fig. 5.4

- (i) The scientists carried out a Pearson's linear correlation calculation for the data in Fig. 5.4.

The scientists calculated an r value of 0.930.

The scientists concluded that there is a significant correlation between the number of tourists visiting the Galápagos islands each year and the number of invasive alien species present.

Table 5.1 shows a probability table of critical values for Pearson’s linear correlation.

Table 5.1

number of observations	probability level (<i>p</i>)	
	0.05	0.01
3	0.997	1.000
4	0.950	0.990
5	0.878	0.959
6	0.811	0.917
7	0.754	0.875

With reference to Table 5.1, explain why the *r* value of 0.930 indicates that there is a significant correlation between the number of tourists and the number of invasive alien species.

.....

.....

.....

..... [2]

(ii) Invasive alien species are thought to have contributed to extinctions recorded in the Galápagos islands.

Discuss the negative effects of introducing invasive alien species to an ecosystem.

.....

.....

.....

.....

.....

.....

.....

.....

..... [4]

(iii) State **two** factors, other than competition and the introduction of invasive alien species, that can cause extinction.

- 2

17.3 Evolution

Name: _____ Class: _____ Date: _____

Total: 12 marks**KEY WORDS** sequence 序列 • speciation 物种形成 • species 物种 • evolution 进化 • allopatric 异域

Objective

Build the skills to answer exam questions on **evolution** — the theory of evolution, **DNA sequence** 序列 evidence, and **speciation** 物种形成 by genetic isolation.

You must be able to:

- outline evolution as the change in gene pools producing new species over time
- discuss how DNA sequence data shows evolutionary relationships
- explain allopatric and sympatric speciation

1 Worked examples

■ Evolution and DNA evidence

Evolution 进化 is the formation of new **species** 物种 from earlier ones as the **gene pool** 基因库 (all the alleles in a population) changes over generations. **DNA sequence data** shows relationships: the more similar two species' DNA, the more recently they shared a common ancestor.

■ Speciation

Allopatric speciation needs a physical barrier; sympatric speciation happens in the same area

directional: favors one extreme · stabilising: favors mean · disruptive: favors both extremes

Selection drives evolution and speciation

Speciation happens when two populations become genetically **isolated** 隔离 so they can no longer interbreed:

- **allopatric** 异域 — separated by a **geographical** barrier (sea, mountain).
- **sympatric** 同域 — in the same area, separated by behaviour or way of life.

2 Practice

2.1 Define **evolution** in terms of the gene pool.

[2]

2.2 State the difference between allopatric and sympatric speciation.

[2]

3 Exam-style questions

3.1 Two species share a very similar DNA base sequence. This suggests they:

[1]

- **A** are not related
- **B** shared a recent common ancestor
- **C** live in the same habitat
- **D** have the same number of chromosomes

3.2 A mountain range divides a population into two, which slowly become different

species. This is:

[1]

- **A** allopatric speciation
 - **B** sympatric speciation
 - **C** genetic drift
 - **D** artificial selection
-

3.3 Explain how allopatric speciation can lead to the formation of two new species. [4]

3.4 Explain how comparing DNA sequences can be used to show how closely related different species are. [2]

Solutions

2.1 evolution is the change in the gene pool / allele frequencies of a population over many generations, leading to new species.

2.2 allopatric — populations separated by a geographical barrier; sympatric — populations in the same area separated by behaviour/ecology.

3.1 B. Very similar DNA suggests a recent common ancestor.

3.2 A. A geographical barrier causing speciation is allopatric.

3.3 a geographical barrier separates the population into two; each population faces different conditions and undergoes different selection / mutations / drift; their gene pools change in different ways; eventually they are so different they can no longer interbreed to produce fertile offspring — two species.

3.4 the more similar the DNA base sequences, the more recently the species shared a common ancestor; large differences indicate they diverged longer ago.

- 4 Alleles are alternative forms of a gene. For example, there may be a dominant allele, **T**, and a recessive allele, **t**, at the same gene locus.

The relative frequency of each allele of a gene in a population can change over time due to factors such as selection, genetic drift and the bottleneck effect.

- (a) Fig. 4.1 shows the relative frequency of the **T** allele in a population of 50 individuals over 20 generations.

At generation 0, the number of **T** alleles and the number of **t** alleles in the population was equal, so the relative frequency of each allele was 0.5. The relative frequencies of the two alleles of the gene add up to 1.

Fig. 4.1

- (i) With reference to Fig. 4.1, state the relative frequency of the **t** allele after 20 generations.

..... [1]

Name:

- (ii) Suggest possible explanations for the change in the relative frequency of the **T** allele between generation 0 and generation 13.

[4]

(c) State the name of the principle that can be used to calculate relative frequencies of two alleles by counting the numbers of organisms in the population showing dominant and recessive phenotypes.

..... [1]

[Total: 9]

- 3 Porphyria is a group of rare genetic diseases in which molecules called porphyrins accumulate in the body.

Three examples of porphyria are:

- X-linked protoporphyria
- variegate porphyria
- congenital erythropoietic porphyria (CEP).

- (a) X-linked protoporphyria is caused by a mutant allele located on the X chromosome.

Fig. 3.1 shows the pattern of inheritance of X-linked protoporphyria in one family.

Fig. 3.1

X-linked protoporphyria is described as a sex-linked disease.

Use the information in Fig. 3.1 to make **one** other conclusion about the pattern of inheritance of X-linked protoporphyria.

Give evidence to support your conclusion.

conclusion

evidence

.....

.....

.....

.....

[2]

(b) Variegate porphyria occurs in 1 in 100 000 people in Europe.

In the 1600s, approximately 100 Dutch people migrated from Europe to South Africa.

The population of people of Dutch descent in South Africa is now 2.5 million. Variegate porphyria occurs in 1 in 1000 people in this population.

Suggest **and** explain why variegate porphyria is more common among people of Dutch descent in South Africa than among people in Europe.

..... [3]

(c) Microarrays can be used to detect various forms of porphyria caused by mutant alleles.

Describe how microarrays can be used to detect a disease by analysing gene expression.

[4]

- (d) The nucleotide sequences of alleles that cause rare genetic diseases, such as the various forms of porphyria, are stored in a database.

State **one** benefit of having a database of nucleotide sequences for alleles that cause rare diseases.

.....
.....
..... [1]

- (e) Congenital erythropoietic porphyria (CEP) is caused by a substitution mutation in a gene coding for an enzyme.

The mutant CEP allele codes for an enzyme with little or no function.

Scientists used gene editing in the laboratory to correct the nucleotide sequence of the mutant allele in cultured human cells.

The scientists introduced three molecules to the cells:

- an enzyme called Cas9 that causes breaks in DNA strands
- guide RNA (gRNA), attached to Cas9, that is complementary to the mutant CEP allele
- a short length of DNA, known as template DNA, that can replace the section of the allele where the substitution mutation has occurred.

The repair mechanism within the cell allows the template DNA to be inserted so that the mutation is corrected.

Fig. 3.2 shows part of the nucleotide sequence in the mutated CEP allele before and after the gene editing procedure.

T A T G G C T C G $\xrightarrow{\text{gene editing}}$ T A C G G C T C G

Fig. 3.2

In the future, this gene editing procedure may be used in a person with CEP to prevent the accumulation of porphyrins in the body.

Suggest **and** explain how this gene editing procedure will prevent the accumulation of porphyrins in a person with CEP without damaging other genes.
