

Organic synthesis

A-Level Chemistry

Organic synthesis

Like the AS synthesis topic, this asks you to **join up** known reactions to build a target molecule. Now you also have the A Level reactions of arenes, phenol, amines, amides and acyl chlorides.

Identifying functional groups

A molecule may carry several **functional group** 官能团 types. Use the test reactions to spot each one, then predict its behaviour. For example:

- decolourises bromine water with **no** catalyst, giving a white precipitate → a phenol or a phenylamine (the ring is activated).
- reacts violently with cold water, giving fumes of HCl → an **acyl chloride** 酰氯.
- gives a purple colour with neutral FeCl₃ → a **phenol** 苯酚.

add this	you see	functional group
bromine water (no catalyst)	white precipitate	phenol or phenylamine
cold water	violent, HCl fumes	acyl chloride
neutral FeCl ₃	purple colour	phenol

Identification tests added at A Level: each reagent gives a characteristic result that points to a functional group

A map of the A Level reactions

Start	Reagent and conditions	Product
benzene (an arene 芳烃)	HNO ₃ / H ₂ SO ₄ (electrophilic substitution 亲电取代)	nitrobenzene
nitrobenzene	Sn / conc HCl, then NaOH (reduction 还原)	phenylamine
phenylamine	HNO ₂ , below 10°C	a diazonium salt
diazonium salt	warm water	phenol; or couple with phenol → azo dye
methylbenzene	hot KMnO ₄ (oxidation 氧化)	benzoic acid
carboxylic acid 羧酸	SOCl ₂ or PCl ₅	acyl chloride
acyl chloride	alcohol / phenol	an ester 酯
acyl chloride	ammonia / amine 胺	an amide 酰胺
amide or nitrile 腈	LiAlH ₄	an amine
halogenoalkane	KCN	a nitrile (adds one carbon)

A map of the A Level reactions: the aromatic chain (top) and the acyl-chloride chain (bottom), with their feed-ins. Work backwards from your target

Planning and analysing a route

To devise a **synthetic route** 合成路线, work **backwards** from the target: which single reaction makes it, and from what? Repeat until you reach the starting material, then write each step with its **reagent** 试剂 and conditions.

plan backwards from the target

Plan a route by working backwards from the target, one reaction at a time, until you reach the starting material

When you **analyse** a route, state the type of reaction for each step (for example electrophilic substitution, **addition-elimination** 加成消去, oxidation or reduction) and watch for likely **by-products** 副产物 — for example, making an amine from a halogenoalkane also gives over-substituted amines, lowering the yield.

Worked example. Devise a route from benzene to phenylamine, $\text{C}_6\text{H}_5\text{NH}_2$. Work **backwards**: phenylamine comes from **reducing** nitrobenzene, and nitrobenzene comes from **nitrating** benzene - so the route is two steps. Step 1: benzene with concentrated HNO_3 and concentrated H_2SO_4 at 55°C ; electrophilic substitution gives nitrobenzene (keep below 55°C , or further substitution follows). Step 2: reduce the nitrobenzene with **tin and concentrated HCl**, then add NaOH to free the amine from its salt. There is no direct route - you cannot put an $-\text{NH}_2$ straight onto a ring, which is exactly why this nitrate-then-reduce pair is worth knowing by heart.

Exam tips

- Combine AS and A-level steps and watch for **benzene-ring reactions** and **carbon-count changes**.
- State every **reagent and condition**, and note when a step produces a **racemic mixture**.
- Choose the shortest route that reaches the target functional group.
