

Chemical Bonding

A-Level Chemistry • Topic 3

A-Level Chemistry

Chemical Bonding

What we will cover

- 1 Electronegativity
- 2 Ionic & metallic bonding
- 3 Covalent & coordinate bonds
- 4 Sigma & pi bonds
- 5 Shapes of molecules
- 6 Intermolecular forces

molecules in 3-D

1

Bonding types

Chemical Bonding

↳ Bonding types

Electronegativity

Electronegativity 电负性 is the power of an atom to attract bonding electrons towards itself.

nuclear charge

more protons pull the pair more strongly

atomic radius

closer to the nucleus
⇒ stronger pull

shielding

inner shells
weaken the pull

It **rises** across a period and **falls** down a group. Fluorine is the most electronegative element. A large difference ⇒ ionic; a small difference ⇒ covalent.

Chemical Bonding

↳ Bonding types

Ionic bonding

Ionic bonding 离子键 is the electrostatic attraction between oppositely charged **ions** 离子. A metal gives electrons to a non-metal. The ions pack into a giant **lattice** 晶格 held in every direction.

NaCl: sodium transfers its outer electron to chlorine → Na^+ and a full-octet Cl^- .

Chemical Bonding

↳ Bonding types

Metallic bonding

Metallic bonding 金属键 is the attraction between positive metal ions and a sea of **delocalised electrons** 离域电子. The free electrons explain why metals conduct and are strong.

2 Covalent bonding

Chemical Bonding
└ Covalent bonding

Covalent and coordinate bonds

A **covalent bond** 共价键 is a shared pair of electrons.

In a **coordinate bond** 配位键 (dative) both electrons come from one atom – e.g. N's lone pair makes NH_4^+ .

Chemical Bonding
└ Covalent bonding

Sigma and pi bonds

■ a **sigma bond** σ 键 – head-on **overlap** 重叠

■ a **pi bond** π 键 – sideways p-orbital overlap

Double = $1\sigma + 1\pi$; triple = $1\sigma + 2\pi$. **Hybridisation** 杂化: sp , sp^2 , sp^3 .

Chemical Bonding
└ Covalent bonding

Shapes of molecules

VSEPR

theory 价层电子对互斥理论: electron pairs push apart as far as possible.

A **lone pair** 孤对电子 repels harder than a bonding pair, squeezing the **bond angle** 键角 ($\sim 2.5^\circ$ each) – so NH_3 is 107°, H_2O 104.5°.

3 Intermolecular forces

Chemical Bonding
└ Intermolecular forces

Intermolecular forces

A bond is **polar** 极性 if the atoms differ in electronegativity (a **dipole** 偶极).

- **London forces** 伦敦色散力 – between all molecules; stronger with more electrons
- permanent dipole forces – between polar molecules

Hydrogen bonding

Hydrogen bonding 氢键 forms when H is bonded to N, O or F and meets a lone pair on N, O or F.

It gives water a high **boiling point** 沸点, high **surface tension** 表面张力, and makes ice **less dense** (so it floats).

4

Recap

Worked example – shape of a molecule

Predict the shape and bond angle of NH_3 .

- N has 5 outer electrons: 3 bond pairs + 1 **lone pair** 孤对电子 = 4 **electron pairs**.
- 4 pairs repel to a **tetrahedral** arrangement (109.5°).
- A lone pair repels **more** than a bond pair, so the angle closes.
- Name the shape from the **atoms only**: **pyramidal**, $\approx 107^\circ$.

Count electron **pairs** for the arrangement, then name the shape from the **atoms**. Each lone pair closes the angle by about 2.5° .

Topic 3 – key takeaways

1 Bond types

ionic, metallic, covalent (& coordinate)

2 Sigma & pi

single 1σ ; double $1\sigma 1\pi$; triple $1\sigma 2\pi$

3 Shapes

VSEPR; lone pairs squeeze the angle

4 Forces

London, dipole, hydrogen bonding

Check yourself

- Which is the most electronegative element?
- In a coordinate bond, where do both electrons come from?
- How many sigma and pi bonds in a triple bond?
- Why does ice float on water?

Answers 1. fluorine 2. one atom (a lone pair) 3. one σ and two π 4. hydrogen bonds hold an open structure (less dense)
