1.2 Multimedia

Name: _____ Class: _____ Date: _____ **Total: 41 marks**

KEY WORDS bitmap • pixel • resolution • file size • sampling

Objective

Build the skills to answer exam questions on **multimedia** – how bitmap images and sound are stored, how to calculate their **file size**, and when to use a bitmap or a vector graphic.

You must be able to:

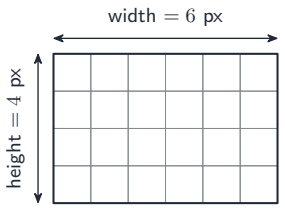

- describe how a **bitmap** image is encoded, and calculate its file size
- explain how **resolution** and **colour depth** affect quality and size
- describe how a **vector graphic** is encoded, and choose bitmap *or* vector for a task
- describe how sound is **sampled**, and how the sampling rate and resolution affect quality and size

1 Worked examples

Study these first. Each one shows the method for a question type used later – follow the steps and you can do the Practice and Exam-style questions yourself.

■ Bitmap images and file size

A **bitmap** image stores the colour of every **pixel** in a grid. Two numbers describe it: the **resolution** (width × height in pixels) and the **colour depth** (bits per pixel). Multiply all three to get the size in bits.

pixels = $6 \times 4 = 24$

size = $24 \times \mathbf{8} = \mathbf{192}$ bits

(**8** = colour depth, bits per pixel)

$$\text{size (bits)} = \text{width} \times \text{height} \times \text{colour depth}$$

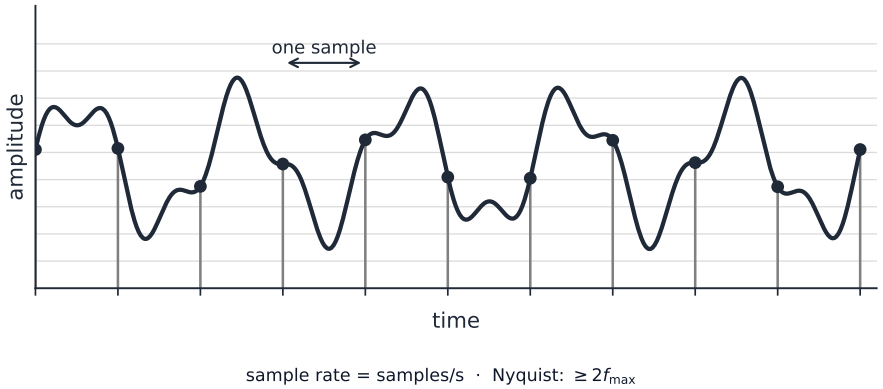

Then ÷ 8 for **bytes**, ÷ 1024 for **KiB**, ÷ 1024 again for **MiB**.

Example. A 200 × 150 image at 8 bits per pixel:

$$200 \times 150 \times 8 = 240\,000 \text{ bits} = 30\,000 \text{ bytes} = \frac{30\,000}{1024} \approx 29.3 \text{ KiB}.$$

■ Sound and file size

Sound is **sampled**: the wave's height (**amplitude**) is measured at regular time intervals. The **sampling rate** is how many samples per second (Hz); the **resolution** is how many bits store each sample.

The faint horizontal lines are the amplitude levels – more bits of resolution means more levels and finer detail.

$$\text{size (bits)} = \text{sampling rate} \times \text{resolution} \times \text{duration} \times \text{channels}$$

Example. A 5-second **mono** (1 channel) clip at 8000 Hz, 16-bit resolution:

$$8000 \times 16 \times 5 \times 1 = 640\,000 \text{ bits} = 80\,000 \text{ bytes} \approx 78.1 \text{ KiB}.$$

■ Bitmap or vector?

A **vector graphic** stores the *instructions* to draw the image – geometric shapes (lines, curves, circles, polygons), each with attributes like position, size, colour and line width. The program draws ("renders") them at whatever size is needed, so a vector **scales without losing quality**. It cannot, however, capture the detail of a photograph.

Task	Better choice	Why
Photograph	**bitmap**	per-pixel detail can't be described as shapes
Logo, icon, road sign	**vector**	sharp at any size; small file
Engineering drawing	**vector**	exact geometry, scales precisely

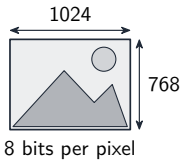

2 Practice

Now apply the methods above.

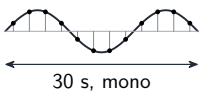

2.1 State what **colour depth** means, and write the formula for a bitmap's file size. [2]

2.2 Calculate the file size of a 1024 × 768 bitmap at 8 bits per pixel. Give your answer in **KiB**, showing your working. [3]

2.3 A 30-second **mono** sound clip is sampled at 16 kHz (16 000 Hz) with 8-bit resolution. Calculate its file size in **KiB**. [3]

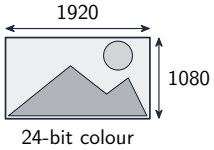

2.4 Give one reason a **vector** graphic is a good choice for a company logo. [1]

3 Exam-style questions

3.1 A photo is 1920 × 1080 pixels with a colour depth of 24 bits.

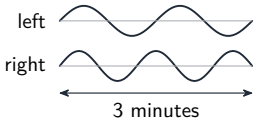

(a) Calculate the file size in **MiB**. Show your working. [3]

(b) State **one** change to the image that would reduce its file size, and explain its effect on quality. [2]

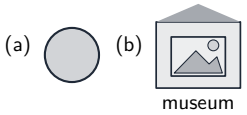

3.2 A 3-minute song is recorded in **stereo** (2 channels), sampled at 44.1 kHz with 16-bit resolution.

(a) Calculate the file size in **MiB**. Show your working. [3]

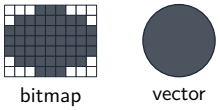

(b) Explain the effect on the recording of **halving** the sampling rate. [2]

3.3 (a) State **two** pieces of data a vector graphic would store to describe a single circle. [2]

(b) A museum scans old paintings to put online. Justify whether a bitmap or a vector format is the better choice. [2]

3.4 Explain why a bitmap logo looks blocky when it is enlarged, but a vector logo stays sharp. [2]

3.5 A school records a 45-second announcement and also stores a scanned photograph of the school badge.

(a) The sound is sampled at 44.1 kHz with a sample resolution of 16 bits, in **stereo** (two channels). **Estimate** the file size in **mebibytes**, showing your working. [4]

(b) The recording is re-sampled at 22.05 kHz with an 8-bit resolution. **Describe** the effect on the file size and on the **accuracy** of the recording. [3]

(c) The badge is stored as a bitmap 600 pixels wide and 400 pixels high, using a colour depth of 24 bits. **Estimate** the file size in **kibibytes**. [3]

(d) **Explain** why the actual file on disk is **larger** than your answer to (c). [2]

(e) The badge uses only 6 distinct colours in large flat areas. **Explain** how **run-length encoding** would compress it, and **state** why it works far better on this image than on a photograph. [4]

Solutions

Each answer shows the steps, then the **result**.

2.1

- colour depth = the number of **bits used per pixel**
- size = width × height × colour depth

2.2

- size in bits = width × height × colour depth

$$1024 \times 768 \times 8 = 6\,291\,456 \text{ bits}$$

- ÷8 for bytes, ÷1024 for KiB

$$\frac{6\,291\,456 \text{ bits}}{8 \times 1024} = \mathbf{768} \text{ KiB}$$

2.3

- size in bits = sampling rate × resolution × duration × channels

$$\text{size (bits)} = \text{sampling rate} \times \text{resolution} \times \text{duration} \times \text{channels}$$

$$16\,000 \text{ Hz} \times 8 \text{ bits} \times 30 \text{ s} \times 1 = 3\,840\,000 \text{ bits}$$

- ÷8 for bytes, ÷1024 for KiB

$$\frac{3\,840\,000 \text{ bits}}{8 \times 1024} = \mathbf{468.75} \text{ KiB}$$

2.4

- any one: it stays **sharp at any size** (a logo is used large and small); the file is small

3.1

(a) size in bits = 1920 × 1080 × 24

$$1920 \times 1080 \times 24 = 49\,766\,400 \text{ bits}$$

- ÷8 ÷ 1024 ÷ 1024 for MiB

$$\frac{49\,766\,400 \text{ bits}}{8 \times 1024 \times 1024} \approx \mathbf{5.93} \text{ MiB}$$

(b) e.g. **lower the colour depth** (or the resolution)

- smaller file, but fewer colours / less detail

3.2

(a) $t = 3$ min $= 180$ s; stereo = 2 channels

- size in bits = rate × resolution × t × channels

$$\text{size (bits)} = \text{sampling rate} \times \text{resolution} \times \text{duration} \times \text{channels}$$

$$44\,100 \text{ Hz} \times 16 \text{ bits} \times 180 \text{ s} \times 2 = 254\,016\,000 \text{ bits}$$

- ÷8 ÷ 1024 ÷ 1024 for MiB

$$\frac{254\,016\,000 \text{ bits}}{8 \times 1024 \times 1024} \approx \mathbf{30.28} \text{ MiB}$$

(b) fewer samples per second

- the file is roughly **half the size**, but high-pitched sounds are lost / quality drops

3.3

(a) any two of: centre position (x, y); radius; line/fill colour; line width

(b) **bitmap**

- a painting has continuous, per-pixel tonal detail that cannot be described as a few shapes

3.4

- a bitmap has a fixed number of pixels; enlarging it makes each pixel bigger, so the squares show
- a vector stores shapes and is **re-drawn** at the new size, so edges stay smooth

3.5

(a) $t = 45$ s; stereo = 2 channels

- size in bits = rate × resolution × t × channels

$$44\,100 \text{ Hz} \times 16 \text{ bits} \times 45 \text{ s} \times 2 = 6.35 \times 10^7 \text{ bits}$$

- ÷8 for bytes

$$\frac{6.35 \times 10^7 \text{ bits}}{8} = 7.94 \times 10^6 \text{ bytes}$$

$$\frac{7.94 \times 10^6 \text{ bytes}}{1\,048\,576 \text{ bytes MiB}^{-1}} = \mathbf{7.6} \text{ MiB}$$

(b) halving both the sampling rate and the resolution divides the size by **four**, to about 1.9 MiB

- the lower rate captures fewer samples per second, so high frequencies are lost
- the smaller resolution records each sample more coarsely, so the waveform is a poorer match and quantisation noise increases

(c) size in bits = width × height × colour depth

$$600 \times 400 \times 24 = 5\,760\,000 \text{ bits} = 720\,000 \text{ bytes}$$

$$\text{KiB} = \frac{\text{bytes}}{1024} = \frac{720\,000 \text{ bytes}}{1024 \text{ bytes KiB}^{-1}} = \mathbf{703} \text{ KiB}$$

(d) the file also stores **metadata** in a header – the dimensions, the colour depth, the file format

- it may include a colour palette or padding, none of which the pixel calculation counts

(e) run-length encoding replaces each run of identical pixels with **one colour value and a count**

- large flat areas of one colour become very short records, so the file shrinks a great deal
- in a photograph adjacent pixels almost always differ slightly
- so runs are one pixel long and the encoding stores a count beside every pixel, which can make the file **bigger** than the original
