1 Variables and data types – Part 1

Name: _____ Class: _____ Date: _____

Vocabulary 词汇

Write each word three times. 把每个单词抄写三遍。

English	中文	Write it 3 times (English)
variable	变量	_____
data type	数据类型	_____
expression	表达式	_____

Recall

You may have written a little code before, or used a calculator app:

- A program stores values and does calculations with them.
- Numbers can be whole (like 5) or decimal (like 2.5).
- Text and numbers are different kinds of data.

This sheet lines up variables and data types in Java. Each idea has a worked example.

New ideas

■ 1 Variables

A **variable** 变量 is a named box that stores a value. You give it a type and a name, then a value:

```
int age = 16;
double price = 2.5;
```

■ 2 Data types

A **data type** 数据类型 says what kind of value a variable holds:

integer	whole number: 7
real	decimal: 3.5
char	one letter: 'A'
string	text: "hello"
boolean	true or false

- **int** – a whole number,
- **double** – a decimal number,
- **boolean** – **true** or **false**,
- **String** – text.

■ 3 Expressions

An **expression** 表达式 combines values with operators (+ - * / %) to compute a result.

Worked example. $3 + 4 * 2$ is 11 (multiply before add), and $10 \% 3$ is 1 (the remainder).

■ 4 Integer division

When you divide two whole numbers, Java throws away the fractional part:

Worked example. $7 / 2$ is 3 (not 3.5), but $7.0 / 2$ is 3.5 (a decimal forces real division).

Watch out: dividing two **int** values **truncates** – $5 / 2$ gives 2, not 2.5. To get a decimal, make one value a **double** first.

Practice

Try these in order. The methods are all above.

2.1 State what data type you would use for (a) a person's age, (b) their height in metres, (c) whether they passed. ^[3]

2.2 Evaluate $2 + 3 * 4$.

[2]

2.3 Evaluate $9 / 2$ and $9 \% 2$.

[2]

2.4 Evaluate $9.0 / 2$.

[1]

2.5 Explain why $1 / 2$ gives 0 in Java.

[2]

Name:

AP Computer Science A: 2016

4. This question involves the process of taking a list of words, called `wordList`, and producing a formatted string of a specified length. The list `wordList` contains at least two words, consisting of letters only.

When the formatted string is constructed, spaces are placed in the gaps between words so that as many spaces as possible are evenly distributed to each gap. The equal number of spaces inserted into each gap is referred to as the *basic gap width*. Any *leftover spaces* are inserted one at a time into the gaps from left to right until there are no more leftover spaces.

The following three examples illustrate these concepts. In each example, the list of words is to be placed into a formatted string of length 20.

Example 1: `wordList`: ["AP", "COMP", "SCI", "ROCKS"]

Total number of letters in words: 14

Number of gaps between words: 3

Basic gap width: 2

Leftover spaces: 0

Formatted string:

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19																
	A		P					C		O		M		P				S		C		I				R		O		C		K		S	

Example 2: `wordList`: ["GREEN", "EGGS", "AND", "HAM"]

Total number of letters in words: 15

Number of gaps between words: 3

Basic gap width: 1

Leftover spaces: 2

The leftover spaces are inserted one at a time between the words from left to right until there are no more leftover spaces. In this example, the first two gaps get an extra space.

Formatted string:

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19																
	G		R		E		E		N				E		G		G		S				A		N		D			H		A		M	

Example 3: `wordList`: ["BEACH", "BALL"]

Total number of letters in words: 9

Number of gaps between words: 1

Basic gap width: 11

Leftover spaces: 0

Formatted string:

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19						
	B		E		A		C		H									B		A		L		L	

You will implement three `static` methods in a class named `StringFormatter` that is not shown.

- (a) Write the `StringFormatter` method `totalLetters`, which returns the total number of letters in the words in its parameter `wordList`. For example, if the variable `List<String> words` is `["A", "frog", "is"]`, then the call `StringFormatter.totalLetters(words)` returns 7. You may assume that all words in `wordList` consist of one or more letters.

Complete method `totalLetters` below.

```
/** Returns the total number of letters in wordList.
 * Precondition: wordList contains at least two words, consisting of letters only.
 */
public static int totalLetters(List<String> wordList)
```

Part (b) begins on page 20.

- (b) Write the `StringFormatter` method `basicGapWidth`, which returns the basic gap width as defined earlier.

Class information for this question

```
public class StringFormatter

public static int totalLetters(List<String> wordList)
public static int basicGapWidth(List<String> wordList,
                                int formattedLen)
public static int leftoverSpaces(List<String> wordList,
                                int formattedLen)
public static String format(List<String> wordList, int formattedLen)
```

WRITE YOUR SOLUTION ON THE NEXT PAGE.

Assume that `totalLetters` works as specified regardless of what you wrote in part (a). You must use `totalLetters` appropriately to receive full credit.

Complete method `basicGapWidth` below.

```
/** Returns the basic gap width when wordList is used to produce
 * a formatted string of formattedLen characters.
 * Precondition: wordList contains at least two words, consisting of letters only.
 * formattedLen is large enough for all the words and gaps.
 */
public static int basicGapWidth(List<String> wordList,
                               int formattedLen)
```

Part (c) begins on page 22.

- (c) Write the `StringFormatter` method `format`, which returns the formatted string as defined earlier. The `StringFormatter` class also contains a method called `leftoverSpaces`, which has already been implemented. This method returns the number of leftover spaces as defined earlier and is shown below.

```
/** Returns the number of leftover spaces when wordList is used to produce
 * a formatted string of formattedLen characters.
 * Precondition: wordList contains at least two words, consisting of letters only.
 * formattedLen is large enough for all the words and gaps.
 */
public static int leftoverSpaces(List<String> wordList,
                                int formattedLen)
{ /* implementation not shown */ }
```

Class information for this question

```
public class StringFormatter

public static int totalLetters(List<String> wordList)
public static int basicGapWidth(List<String> wordList,
                                int formattedLen)
public static int leftoverSpaces(List<String> wordList,
                                int formattedLen)
public static String format(List<String> wordList, int formattedLen)
```

WRITE YOUR SOLUTION ON THE NEXT PAGE.

Assume that `basicGapWidth` works as specified, regardless of what you wrote in part (b). You must use `basicGapWidth` and `leftoverSpaces` appropriately to receive full credit.

Complete method `format` below.

```
/** Returns a formatted string consisting of the words in wordList separated by spaces.
 * Precondition: The wordList contains at least two words, consisting of letters only.
 *                 formattedLen is large enough for all the words and gaps.
 * Postcondition: All words in wordList appear in the formatted string.
 *   - The words appear in the same order as in wordList.
 *   - The number of spaces between words is determined by basicGapWidth and the
 *     distribution of leftoverSpaces from left to right, as described in the question.
 */
public static String format(List<String> wordList, int formattedLen)
```

STOP
END OF EXAM

1 Objects, Strings, and methods – Part 2

Name: _____ Class: _____ Date: _____

Vocabulary 词汇

Write each word three times. 把每个单词抄写三遍。

English	中文	Write it 3 times (English)
object	对象	_____
method	方法	_____

Recall

In Part A you met variables and types. Now meet **objects** and how to use them:

- An object is a "thing" in a program, like a piece of text (a **String**).
- You do things to an object by calling its methods.

Each idea has a worked example before the Practice.

New ideas

■ 1 Objects

An **object** 对象 bundles data with actions (methods). You create one with **new**:

```
Scanner in = new Scanner(System.in);
String s = "COMPUTER";
```

class = blueprint (type) · object = instance with its own field values

■ 2 Calling a method

A **method** 方法 is an action you run on an object, written `object.method(...)`:

```
s.length();    // how many characters
s.substring(0,4); // part of the text
```

■ 3 Strings

A **String** is text, and its characters are numbered from 0.

"COMPUTER".substring(0, 4) → "COMP"

valid indices: 0 ... `s.length() - 1` · `s.charAt(i)` is the char at `i`

Worked example. For `String s = "COMPUTER"`: `s.length()` is 8; `s.substring(0,4)` is "COMP" (characters 0,1,2,3, index 4 excluded).

■ 4 Comparing text

Use `.equals(...)` to compare Strings, not `==`.

Watch out: `s.substring(a, b)` includes index `a` but **excludes** `b`. And String characters count from 0, so the first character is index 0, not 1.

Practice

Try these in order. The methods are all above. Use `String s = "PROGRAM";` (indices 0–6).

2.1 State what an object is, in your own words. [2]

2.2 Find `s.length()`. [1]

2.3 Find `s.substring(0,4)`. [2]

2.4 Find `s.substring(3)` (from index 3 to the end). [2]

2.5 State which character is at index 0 of `s`. [1]

1. This question involves dog walkers who are paid through a dog-walking company to take dogs for one-hour walks. A dog-walking company has a varying number of dogs that need to be walked during each hour of the day. A dog-walking company is represented by the following `DogWalkCompany` class.

```
public class DogWalkCompany
{
    /**
     * Returns the number of dogs, always greater than 0, that are available
     * for a walk during the time specified by hour
     * Precondition: 0 <= hour <= 23
     */
    public int numAvailableDogs(int hour)
    { /* implementation not shown */ }

    /**
     * Decreases, by numberDogsWalked, the number of dogs available for a walk
     * during the time specified by hour
     * Preconditions: 0 <= hour <= 23
     *                 numberDogsWalked > 0
     */
    public void updateDogs(int hour, int numberDogsWalked)
    { /* implementation not shown */ }

    /* There may be instance variables, constructors,
       and methods that are not shown. */
}
```

A dog walker is associated with a dog-walking company and is represented by the `DogWalker` class. You will write two methods of the `DogWalker` class.

```
public class DogWalker
{
    /** The maximum number of dogs this walker can walk simultaneously
        per hour */
    private int maxDogs;

    /** The dog-walking company this dog walker is associated with */
    private DogWalkCompany company;

    /**
     * Assigns max to maxDogs and comp to company
     * Precondition: max > 0
     */
    public DogWalker(int max, DogWalkCompany comp)
    { /* implementation not shown */ }

    /**
     * Takes at least one dog for a walk during the time specified by
     * hour, as described in part (a)
     * Preconditions: 0 <= hour <= 23
     *                 maxDogs > 0
     */
    public int walkDogs(int hour)
    { /* to be implemented in part (a) */ }
```

```

/**
 * Performs an entire dog-walking shift and returns the amount
 * earned, in dollars, as described in part (b)
 * Preconditions: 0 <= startHour <= endHour <= 23
 *               maxDogs > 0
 */
public int dogWalkShift(int startHour, int endHour)
{ /* to be implemented in part (b) */ }

/* There may be instance variables, constructors,
   and methods that are not shown. */
}

```

- A. Write the `walkDogs` method, which updates and returns the number of dogs this dog walker walks during the time specified by `hour`. Values of `hour` range from 0 to 23, inclusive.

A helper method, `numAvailableDogs`, has been provided in the `DogWalkCompany` class. The method returns the number of dogs available to be taken for a walk at a given hour. The dog walker will always walk as many dogs as the dog-walking company has available to walk, as long as the available number of dogs is not greater than the maximum number of dogs that the dog walker can handle, represented by the value of `maxDogs`.

Another helper method, `updateDogs`, has also been provided in the `DogWalkCompany` class. So that multiple dog walkers do not sign up to walk the same dogs, the `walkDogs` method should use `updateDogs` to update the dog-walking company with the number of dogs this dog walker will walk during the given hour. The parameters of the `updateDogs` method indicate how many dogs this dog walker will walk during the time specified by `hour`.

For example, if the dog-walking company has 10 dogs that need to be walked at the given hour but the dog walker's maximum is 4, the `updateDogs` method should be used to indicate that this dog walker will walk 4 of the 10 dogs during the given hour. As another example, if the dog-walking company has 3 dogs that need to be walked at the given hour and the dog walker's maximum is 4, the `updateDogs` method should be used to indicate that this dog walker will walk all 3 of the available dogs during the given hour.

The `walkDogs` method should return the number of dogs to be walked by this dog walker during the time specified by `hour`.

Complete method `walkDogs`. You must use `numAvailableDogs` and `updateDogs` appropriately to receive full credit.

```

/**
 * Takes at least one dog for a walk during the time specified by
 * hour, as described in part (a)
 * Preconditions: 0 <= hour <= 23
 *               maxDogs > 0
 */
public int walkDogs(int hour)

```

- B. Write the `dogWalkShift` method, which performs a dog-walking shift of the hours in the range `startHour` to `endHour`, inclusive, and returns the total amount earned. For example, a dog-walking shift from 14 to 16 is composed of three one-hour dog walks starting at hours 14, 15, and 16.

For each hour, the base pay is \$5 per dog walked plus a bonus of \$3 if at least one of the following is true.

- `maxDogs` dogs are walked
- the walk occurs between the peak hours of 9 and 17, inclusive

The following table shows an example of the calculated amount earned by walking dogs from hour 7 through hour 10, inclusive.

Hour	Maximum Number of Dogs	Number of Dogs Walked	Amount Earned, in Dollars
7	3	3	$3 \times 5 + 3 = 18$
8	3	2	$2 \times 5 = 10$
9	3	2	$2 \times 5 + 3 = 13$
10	3	3	$3 \times 5 + 3 = 18$
Total			59

Complete method `dogWalkShift`. Assume that `walkDogs` works as specified, regardless of what you wrote in part (a). You must use `walkDogs` appropriately to earn full credit.

```
/**
 * Performs an entire dog-walking shift and returns the amount
 * earned, in dollars, as described in part (b)
 * Preconditions: 0 <= startHour <= endHour <= 23
 *               maxDogs > 0
 */
public int dogWalkShift(int startHour, int endHour)
```

3. The `StringChecker` interface describes classes that check if strings are valid, according to some criterion.

```
public interface StringChecker
{
    /** Returns true if str is valid. */
    boolean isValid(String str);
}
```

A `CodeWordChecker` is a `StringChecker`. A `CodeWordChecker` object can be constructed with three parameters: two integers and a string. The first two parameters specify the minimum and maximum code word lengths, respectively, and the third parameter specifies a string that must not occur in the code word. A `CodeWordChecker` object can also be constructed with a single parameter that specifies a string that must not occur in the code word; in this case the minimum and maximum lengths will default to 6 and 20, respectively.

The following examples illustrate the behavior of `CodeWordChecker` objects.

Example 1

```
StringChecker sc1 = new CodeWordChecker(5, 8, "$");
```

Valid code words have 5 to 8 characters and must not include the string "\$".

Method call	Return value	Explanation
<code>sc1.isValid("happy")</code>	true	The code word is valid.
<code>sc1.isValid("happy\$")</code>	false	The code word contains "\$".
<code>sc1.isValid("Code")</code>	false	The code word is too short.
<code>sc1.isValid("happyCode")</code>	false	The code word is too long.

Example 2

```
StringChecker sc2 = new CodeWordChecker("pass");
```

Valid code words must not include the string "pass". Because the bounds are not specified, the length bounds are 6 and 20, inclusive.

Method call	Return value	Explanation
<code>sc2.isValid("MyPass")</code>	true	The code word is valid.
<code>sc2.isValid("Mypassport")</code>	false	The code word contains "pass".
<code>sc2.isValid("happy")</code>	false	The code word is too short.
<code>sc2.isValid("1,000,000,000,000,000")</code>	false	The code word is too long.

Write the complete `CodeWordChecker` class. Your implementation must meet all specifications and conform to all examples.

2 Making decisions - if and boolean

– Part 1

Name: _____ Class: _____ Date: _____

Vocabulary 词汇

Write each word three times. 把每个单词抄写三遍。

English	中文	Write it 3 times (English)
boolean	布尔	_____

Recall

Programs have to make decisions:

- “If it is raining, take an umbrella.”
- A game checks if your score beats the high score.
- A test is either passed or failed – true or false.

This sheet lines up how programs decide. Each idea has a worked example.

New ideas

■ 1 Boolean values

A **boolean** 布尔 value is either **true** or **false**. Comparisons produce booleans:

== (equal), **!=** (not equal), **<**, **>**, **<=**, **>=**.

Worked example. 5 > 3 is **true**; 4 == 5 is **false**.

■ 2 The if statement

An if statement runs code **only when** a condition is true:

```
if (score >= 50) {  
    System.out.println("Pass");  
}
```

■ 3 if / else

Add **else** to do something when the condition is false:

```
if (score >= 50) System.out.println("Pass");  
else System.out.println("Fail");
```

■ 4 Combining conditions

- **&&** means **and** (both must be true),
- **||** means **or** (at least one is true),
- **!** means **not** (flips true and false).

Watch out: **==** compares two values, but a single **=** assigns a value. Writing **if (x = 5)** is a bug – use **if (x == 5)**.

Practice

Try these in order. The methods are all above.

2.1 State the two possible values of a boolean. [1]

2.2 Evaluate 7 > 4 and 3 == 4. [2]

2.3 Evaluate (5 > 3) && (2 > 4). [2]

2.4 A student has `score = 80`. State what `if (score >= 50)` prints given the if/else above. [1]

2.5 State the difference between `==` and `=`. [2]

1. The `APCalendar` class contains methods used to calculate information about a calendar. You will write two methods of the class.

```
public class APCalendar
{

    /** Returns true if year is a leap year and false otherwise. */
    private static boolean isLeapYear(int year)
    { /* implementation not shown */ }

    /** Returns the number of leap years between year1 and year2, inclusive.
     * Precondition: 0 <= year1 <= year2
     */
    public static int numberOfLeapYears(int year1, int year2)
    { /* to be implemented in part (a) */ }

    /** Returns the value representing the day of the week for the first day of year,
     * where 0 denotes Sunday, 1 denotes Monday, ..., and 6 denotes Saturday.
     */
    private static int firstDayOfYear(int year)
    { /* implementation not shown */ }

    /** Returns n, where month, day, and year specify the nth day of the year.
     * Returns 1 for January 1 (month = 1, day = 1) of any year.
     * Precondition: The date represented by month, day, year is a valid date.
     */
    private static int dayOfYear(int month, int day, int year)
    { /* implementation not shown */ }

    /** Returns the value representing the day of the week for the given date
     * (month, day, year), where 0 denotes Sunday, 1 denotes Monday, ...,
     * and 6 denotes Saturday.
     * Precondition: The date represented by month, day, year is a valid date.
     */
    public static int dayOfWeek(int month, int day, int year)
    { /* to be implemented in part (b) */ }

    // There may be instance variables, constructors, and other methods not shown.

}
```

- (a) Write the static method `numberOfLeapYears`, which returns the number of leap years between `year1` and `year2`, inclusive.

In order to calculate this value, a helper method is provided for you.

- `isLeapYear(year)` returns `true` if `year` is a leap year and `false` otherwise.

Complete method `numberOfLeapYears` below. You must use `isLeapYear` appropriately to receive full credit.

```
/** Returns the number of leap years between year1 and year2, inclusive.
 * Precondition: 0 <= year1 <= year2
 */
public static int numberOfLeapYears(int year1, int year2)
```

- (b) Write the static method `dayOfWeek`, which returns the integer value representing the day of the week for the given date (`month`, `day`, `year`), where 0 denotes Sunday, 1 denotes Monday, ..., and 6 denotes Saturday. For example, 2019 began on a Tuesday, and January 5 is the fifth day of 2019. As a result, January 5, 2019, fell on a Saturday, and the method call `dayOfWeek(1, 5, 2019)` returns 6.

As another example, January 10 is the tenth day of 2019. As a result, January 10, 2019, fell on a Thursday, and the method call `dayOfWeek(1, 10, 2019)` returns 4.

In order to calculate this value, two helper methods are provided for you.

- `firstDayOfYear(year)` returns the integer value representing the day of the week for the first day of year, where 0 denotes Sunday, 1 denotes Monday, ..., and 6 denotes Saturday. For example, since 2019 began on a Tuesday, `firstDayOfYear(2019)` returns 2.
- `dayOfYear(month, day, year)` returns n , where `month`, `day`, and `year` specify the n th day of the year. For the first day of the year, January 1 (`month` = 1, `day` = 1), the value 1 is returned. This method accounts for whether `year` is a leap year. For example, `dayOfYear(3, 1, 2017)` returns 60, since 2017 is not a leap year, while `dayOfYear(3, 1, 2016)` returns 61, since 2016 is a leap year.

Class information for this question

```
public class APCalendar
{
    private static boolean isLeapYear(int year)
    public static int numberOfLeapYears(int year1, int year2)
    private static int firstDayOfYear(int year)
    private static int dayOfYear(int month, int day, int year)
    public static int dayOfWeek(int month, int day, int year)
}
```

Complete method `dayOfWeek` below. You must use `firstDayOfYear` and `dayOfYear` appropriately to receive full credit.

```
/** Returns the value representing the day of the week for the given date
 * (month, day, year), where 0 denotes Sunday, 1 denotes Monday, ...,
 * and 6 denotes Saturday.
 * Precondition: The date represented by month, day, year is a valid date.
 */
public static int dayOfWeek(int month, int day, int year)
```

3. A crossword puzzle grid is a two-dimensional rectangular array of black and white squares. Some of the white squares are labeled with a positive number according to the *crossword labeling rule*.

The crossword labeling rule identifies squares to be labeled with a positive number as follows.

A square is labeled with a positive number if and only if

- the square is white and
- the square does not have a white square immediately above it, or it does not have a white square immediately to its left, or both.

The squares identified by these criteria are labeled with consecutive numbers in row-major order, starting at 1.

The following diagram shows a crossword puzzle grid and the labeling of the squares according to the crossword labeling rule.

This question uses two classes, a `Square` class that represents an individual square in the puzzle and a `Crossword` class that represents a crossword puzzle grid. A partial declaration of the `Square` class is shown below.

```
public class Square
{
    /** Constructs one square of a crossword puzzle grid.
     * Postcondition:
     *   - The square is black if and only if isBlack is true.
     *   - The square has number num.
     */
    public Square(boolean isBlack, int num)
    { /* implementation not shown */ }

    // There may be instance variables, constructors, and methods that are not shown.
}
```

A partial declaration of the `Crossword` class is shown below. You will implement one method and the constructor in the `Crossword` class.

```
public class Crossword
{
    /** Each element is a Square object with a color (black or white) and a number.
     *   puzzle[r][c] represents the square in row r, column c.
     *   There is at least one row in the puzzle.
     */
    private Square[][] puzzle;

    /** Constructs a crossword puzzle grid.
     *   Precondition: There is at least one row in blackSquares.
     *   Postcondition:
     *     - The crossword puzzle grid has the same dimensions as blackSquares.
     *     - The Square object at row r, column c in the crossword puzzle grid is black
     *       if and only if blackSquares[r][c] is true.
     *     - The squares in the puzzle are labeled according to the crossword labeling rule.
     */
    public Crossword(boolean[][] blackSquares)
    { /* to be implemented in part (b) */ }

    /** Returns true if the square at row r, column c should be labeled with a positive number;
     *     false otherwise.
     *   The square at row r, column c is black if and only if blackSquares[r][c] is true.
     *   Precondition: r and c are valid indexes in blackSquares.
     */
    private boolean toBeLabeled(int r, int c, boolean[][] blackSquares)
    { /* to be implemented in part (a) */ }

    // There may be instance variables, constructors, and methods that are not shown.
}
```

Part (a) begins on page 14.

- (a) Write the `Crossword` method `toBeLabeled`. The method returns `true` if the square indexed by row `r`, column `c` in a crossword puzzle grid should be labeled with a positive number according to the crossword labeling rule; otherwise it returns `false`. The parameter `blackSquares` indicates which squares in the crossword puzzle grid are black.

Class information for this question

```
public class Square

public Square(boolean isBlack, int num)

public class Crossword

private Square[][] puzzle

public Crossword(boolean[][] blackSquares)
private boolean toBeLabeled(int r, int c, boolean[][] blackSquares)
```

WRITE YOUR SOLUTION ON THE NEXT PAGE.

Complete method `toBeLabeled` below.

```
/** Returns true if the square at row r, column c should be labeled with a positive number;
 *     false otherwise.
 * The square at row r, column c is black if and only if blackSquares[r][c] is true.
 * Precondition: r and c are valid indexes in blackSquares.
 */
private boolean toBeLabeled(int r, int c, boolean[][] blackSquares)
```

Part (b) begins on page 16.

- (b) Write the `Crossword` constructor. The constructor should initialize the crossword puzzle grid to have the same dimensions as the parameter `blackSquares`. Each element of the puzzle grid should be initialized with a reference to a `Square` object with the appropriate color and number. The number is positive if the square is labeled and 0 if the square is not labeled.

Class information for this question

```
public class Square

public Square(boolean isBlack, int num)

public class Crossword

private Square[][] puzzle

public Crossword(boolean[][] blackSquares)
private boolean toBeLabeled(int r, int c, boolean[][] blackSquares)
```

WRITE YOUR SOLUTION ON THE NEXT PAGE.

Assume that `toBeLabeled` works as specified, regardless of what you wrote in part (a). You must use `toBeLabeled` appropriately to receive full credit.

Complete the `Crossword` constructor below.

```
/** Constructs a crossword puzzle grid.
 * Precondition: There is at least one row in blackSquares.
 * Postcondition:
 * - The crossword puzzle grid has the same dimensions as blackSquares.
 * - The Square object at row r, column c in the crossword puzzle grid is black
 *   if and only if blackSquares[r][c] is true.
 * - The squares in the puzzle are labeled according to the crossword labeling rule.
 */
public Crossword(boolean[][] blackSquares)
```

1. This question involves the `WordMatch` class, which stores a secret string and provides methods that compare other strings to the secret string. You will write two methods in the `WordMatch` class.

```
public class WordMatch
{
    /** The secret string. */
    private String secret;

    /** Constructs a WordMatch object with the given secret string of lowercase letters. */
    public WordMatch(String word)
    {
        /* implementation not shown */
    }

    /** Returns a score for guess, as described in part (a).
     *   Precondition:  $0 < \text{guess.length}() \leq \text{secret.length}()$ 
     */
    public int scoreGuess(String guess)
    { /* to be implemented in part (a) */ }

    /** Returns the better of two guesses, as determined by scoreGuess and the rules for a
     *   tie-breaker that are described in part (b).
     *   Precondition: guess1 and guess2 contain all lowercase letters.
     *           guess1 is not the same as guess2.
     */
    public String findBetterGuess(String guess1, String guess2)
    { /* to be implemented in part (b) */ }
}
```

- (a) Write the `WordMatch` method `scoreGuess`. To determine the score to be returned, `scoreGuess` finds the number of times that `guess` occurs as a substring of `secret` and then multiplies that number by the square of the length of `guess`. Occurrences of `guess` may overlap within `secret`.

Assume that the length of `guess` is less than or equal to the length of `secret` and that `guess` is not an empty string.

The following examples show declarations of a `WordMatch` object. The tables show the outcomes of some possible calls to the `scoreGuess` method.

```
WordMatch game = new WordMatch("mississippi");
```

Value of <code>guess</code>	Number of Substring Occurrences	Score Calculation: (Number of Substring Occurrences) x (Square of the Length of <code>guess</code>)	Return Value of <code>game.scoreGuess(guess)</code>
"i"	4	$4 * 1 * 1 = 4$	4
"iss"	2	$2 * 3 * 3 = 18$	18
"issipp"	1	$1 * 6 * 6 = 36$	36
"mississippi"	1	$1 * 11 * 11 = 121$	121

```
WordMatch game = new WordMatch("aaaabb");
```

Value of <code>guess</code>	Number of Substring Occurrences	Score Calculation: (Number of Substring Occurrences) x (Square of the Length of <code>guess</code>)	Return Value of <code>game.scoreGuess(guess)</code>
"a"	4	$4 * 1 * 1 = 4$	4
"aa"	3	$3 * 2 * 2 = 12$	12
"aaa"	2	$2 * 3 * 3 = 18$	18
"aabb"	1	$1 * 4 * 4 = 16$	16
"c"	0	$0 * 1 * 1 = 0$	0

Complete the `scoreGuess` method.

```
/** Returns a score for guess, as described in part (a).
 * Precondition: 0 < guess.length() <= secret.length()
 */
public int scoreGuess(String guess)
```

Begin your response at the top of a new page in the separate Free Response booklet and fill in the appropriate circle at the top of each page to indicate the question number. If there are multiple parts to this question, write the part letter with your response.

Class information for this question

```
public class WordMatch

private String secret

public WordMatch(String word)
public int scoreGuess(String guess)
public String findBetterGuess(String guess1, String guess2)
```

- (b) Write the `WordMatch` method `findBetterGuess`, which returns the better guess of its two `String` parameters, `guess1` and `guess2`. If the `scoreGuess` method returns different values for `guess1` and `guess2`, then the guess with the higher score is returned. If the `scoreGuess` method returns the same value for `guess1` and `guess2`, then the alphabetically greater guess is returned.

The following example shows a declaration of a `WordMatch` object and the outcomes of some possible calls to the `scoreGuess` and `findBetterGuess` methods.

```
WordMatch game = new WordMatch("concatenation");
```

Method Call	Return Value	Explanation
<code>game.scoreGuess("ten");</code>	9	1 * 3 * 3
<code>game.scoreGuess("nation");</code>	36	1 * 6 * 6
<code>game.findBetterGuess("ten", "nation");</code>	"nation"	Since <code>scoreGuess</code> returns 36 for "nation" and 9 for "ten", the guess with the greater score, "nation", is returned.
<code>game.scoreGuess("con");</code>	9	1 * 3 * 3
<code>game.scoreGuess("cat");</code>	9	1 * 3 * 3
<code>game.findBetterGuess("con", "cat");</code>	"con"	Since <code>scoreGuess</code> returns 9 for both "con" and "cat", the alphabetically greater guess, "con", is returned.

Complete method `findBetterGuess`.

Assume that `scoreGuess` works as specified, regardless of what you wrote in part (a). You must use `scoreGuess` appropriately to receive full credit.

```
/** Returns the better of two guesses, as determined by scoreGuess and the rules for a
 * tie-breaker that are described in part (b).
 * Precondition: guess1 and guess2 contain all lowercase letters.
 * guess1 is not the same as guess2.
 */
public String findBetterGuess(String guess1, String guess2)
```

Begin your response at the top of a new page in the separate Free Response booklet and fill in the appropriate circle at the top of each page to indicate the question number. If there are multiple parts to this question, write the part letter with your response.

Class information for this question

```
public class WordMatch

private String secret

public WordMatch(String word)
public int scoreGuess(String guess)
public String findBetterGuess(String guess1, String guess2)
```

1. This question involves reasoning about a simulation of a frog hopping in a straight line. The frog attempts to hop to a goal within a specified number of hops. The simulation is encapsulated in the following `FrogSimulation` class. You will write two of the methods in this class.

```
public class FrogSimulation
{
    /** Distance, in inches, from the starting position to the goal. */
    private int goalDistance;

    /** Maximum number of hops allowed to reach the goal. */
    private int maxHops;

    /** Constructs a FrogSimulation where dist is the distance, in inches, from the starting
     * position to the goal, and numHops is the maximum number of hops allowed to reach the goal.
     * Precondition: dist > 0; numHops > 0
     */
    public FrogSimulation(int dist, int numHops)
    {
        goalDistance = dist;
        maxHops = numHops;
    }

    /** Returns an integer representing the distance, in inches, to be moved when the frog hops.
     */
    private int hopDistance()
    { /* implementation not shown */ }

    /** Simulates a frog attempting to reach the goal as described in part (a).
     * Returns true if the frog successfully reached or passed the goal during the simulation;
     * false otherwise.
     */
    public boolean simulate()
    { /* to be implemented in part (a) */ }

    /** Runs num simulations and returns the proportion of simulations in which the frog
     * successfully reached or passed the goal.
     * Precondition: num > 0
     */
    public double runSimulations(int num)
    { /* to be implemented in part (b) */ }
```

- (a) Write the `simulate` method, which simulates the frog attempting to hop in a straight line to a goal from the frog's starting position of 0 within a maximum number of hops. The method returns `true` if the frog successfully reached the goal within the maximum number of hops; otherwise, the method returns `false`.

The `FrogSimulation` class provides a method called `hopDistance` that returns an integer representing the distance (positive or negative) to be moved when the frog hops. A positive distance represents a move toward the goal. A negative distance represents a move away from the goal. The returned distance may vary from call to call. Each time the frog hops, its position is adjusted by the value returned by a call to the `hopDistance` method.

The frog hops until one of the following conditions becomes true:

- The frog has reached or passed the goal.
- The frog has reached a negative position.
- The frog has taken the maximum number of hops without reaching the goal.

The following example shows a declaration of a `FrogSimulation` object for which the goal distance is 24 inches and the maximum number of hops is 5. The table shows some possible outcomes of calling the `simulate` method.

```
FrogSimulation sim = new FrogSimulation(24, 5);
```

	Values returned by <code>hopDistance()</code>	Final position of frog	Return value of <code>sim.simulate()</code>
Example 1	5, 7, -2, 8, 6	24	<code>true</code>
Example 2	6, 7, 6, 6	25	<code>true</code>
Example 3	6, -6, 31	31	<code>true</code>
Example 4	4, 2, -8	-2	<code>false</code>
Example 5	5, 4, 2, 4, 3	18	<code>false</code>

Class information for this question

```
public class FrogSimulation

private int goalDistance
private int maxHops

private int hopDistance()
public boolean simulate()
public double runSimulations(int num)
```

Complete method `simulate` below. You must use `hopDistance` appropriately to receive full credit.

```
/** Simulates a frog attempting to reach the goal as described in part (a).
 * Returns true if the frog successfully reached or passed the goal during the simulation.
```

- (b) Write the `runSimulations` method, which performs a given number of simulations and returns the proportion of simulations in which the frog successfully reached or passed the goal. For example, if the parameter passed to `runSimulations` is 400, and 100 of the 400 `simulate` method calls returned `true`, then the `runSimulations` method should return 0.25.

Complete method `runSimulations` below. Assume that `simulate` works as specified, regardless of what you wrote in part (a). You must use `simulate` appropriately to receive full credit.

```
/** Runs num simulations and returns the proportion of simulations in which the frog
 * successfully reached or passed the goal.
```

2 Loops – Part 2

Name: _____ Class: _____ Date: _____

Vocabulary 词汇

Write each word three times. 把每个单词抄写三遍。

English	中文	Write it 3 times (English)
while loop	循环	_____

Recall

In Part A you met decisions. Now make the computer **repeat** work:

- Printing the numbers 1 to 100 by hand would be slow.
- A loop repeats the same steps many times, quickly.

Each idea has a worked example before the Practice.

New ideas

■ 1 The while loop

A **while loop** 循环 repeats **while** its condition is true:

```
int i = 0;
while (i < 3) {
    System.out.println(i);
    i++;
}
```

This prints 0, 1, 2.

■ 2 The for loop

A **for** loop packs the setup, condition, and update into one line – best when you know the count:

```
for (int i = 0; i < 5; i++) {
    // runs 5 times: i = 0,1,2,3,4
}
```

■ 3 Counting the repeats

A loop **for** (int i = 0; i < n; i++) runs exactly n times.

Worked example. **for** (int i = 1; i <= 4; i++) runs 4 times (for i = 1, 2, 3, 4).

■ 4 Nested loops

A loop **inside** another loop runs the inner one fully for each pass of the outer. If the outer runs 3 times and the inner 4, the inside runs 3 × 4 = 12 times.

Watch out: a loop must **change** something each time (like **i++**) so the condition eventually becomes false. If it never does, the loop runs forever – an infinite loop.

Practice

Try these in order. The methods are all above.

2.1 State how many times `for (int i = 0; i < 6; i++)` runs. [1]

2.2 State the values printed by the while loop above (`i` from 0 while `i < 3`). [2]

2.3 State how many times `for (int i = 1; i <= 10; i++)` runs. [2]

2.4 A nested loop has an outer running 5 times and an inner running 3 times. State how many times the inner body runs in total. [2]

2.5 Explain what makes a loop “infinite”. [2]

1. This question involves reasoning about a simulation of a frog hopping in a straight line. The frog attempts to hop to a goal within a specified number of hops. The simulation is encapsulated in the following `FrogSimulation` class. You will write two of the methods in this class.

```
public class FrogSimulation
{
    /** Distance, in inches, from the starting position to the goal. */
    private int goalDistance;

    /** Maximum number of hops allowed to reach the goal. */
    private int maxHops;

    /** Constructs a FrogSimulation where dist is the distance, in inches, from the starting
     * position to the goal, and numHops is the maximum number of hops allowed to reach the goal.
     * Precondition: dist > 0; numHops > 0
     */
    public FrogSimulation(int dist, int numHops)
    {
        goalDistance = dist;
        maxHops = numHops;
    }

    /** Returns an integer representing the distance, in inches, to be moved when the frog hops.
     */
    private int hopDistance()
    { /* implementation not shown */ }

    /** Simulates a frog attempting to reach the goal as described in part (a).
     * Returns true if the frog successfully reached or passed the goal during the simulation;
     * false otherwise.
     */
    public boolean simulate()
    { /* to be implemented in part (a) */ }

    /** Runs num simulations and returns the proportion of simulations in which the frog
     * successfully reached or passed the goal.
     * Precondition: num > 0
     */
    public double runSimulations(int num)
    { /* to be implemented in part (b) */ }
```

- (a) Write the `simulate` method, which simulates the frog attempting to hop in a straight line to a goal from the frog's starting position of 0 within a maximum number of hops. The method returns `true` if the frog successfully reached the goal within the maximum number of hops; otherwise, the method returns `false`.

The `FrogSimulation` class provides a method called `hopDistance` that returns an integer representing the distance (positive or negative) to be moved when the frog hops. A positive distance represents a move toward the goal. A negative distance represents a move away from the goal. The returned distance may vary from call to call. Each time the frog hops, its position is adjusted by the value returned by a call to the `hopDistance` method.

The frog hops until one of the following conditions becomes true:

- The frog has reached or passed the goal.
- The frog has reached a negative position.
- The frog has taken the maximum number of hops without reaching the goal.

The following example shows a declaration of a `FrogSimulation` object for which the goal distance is 24 inches and the maximum number of hops is 5. The table shows some possible outcomes of calling the `simulate` method.

```
FrogSimulation sim = new FrogSimulation(24, 5);
```

	Values returned by <code>hopDistance()</code>	Final position of frog	Return value of <code>sim.simulate()</code>
Example 1	5, 7, -2, 8, 6	24	<code>true</code>
Example 2	6, 7, 6, 6	25	<code>true</code>
Example 3	6, -6, 31	31	<code>true</code>
Example 4	4, 2, -8	-2	<code>false</code>
Example 5	5, 4, 2, 4, 3	18	<code>false</code>

Class information for this question

```
public class FrogSimulation

private int goalDistance
private int maxHops

private int hopDistance()
public boolean simulate()
public double runSimulations(int num)
```

Complete method `simulate` below. You must use `hopDistance` appropriately to receive full credit.

```
/** Simulates a frog attempting to reach the goal as described in part (a).
 * Returns true if the frog successfully reached or passed the goal during the simulation.
```

- (b) Write the `runSimulations` method, which performs a given number of simulations and returns the proportion of simulations in which the frog successfully reached or passed the goal. For example, if the parameter passed to `runSimulations` is 400, and 100 of the 400 `simulate` method calls returned `true`, then the `runSimulations` method should return 0.25.

Complete method `runSimulations` below. Assume that `simulate` works as specified, regardless of what you wrote in part (a). You must use `simulate` appropriately to receive full credit.

```
/** Runs num simulations and returns the proportion of simulations in which the frog
 * successfully reached or passed the goal.
```

1. This question involves reasoning about a simulation of a frog hopping in a straight line. The frog attempts to hop to a goal within a specified number of hops. The simulation is encapsulated in the following `FrogSimulation` class. You will write two of the methods in this class.

```
public class FrogSimulation
{
    /** Distance, in inches, from the starting position to the goal. */
    private int goalDistance;

    /** Maximum number of hops allowed to reach the goal. */
    private int maxHops;

    /** Constructs a FrogSimulation where dist is the distance, in inches, from the starting
     * position to the goal, and numHops is the maximum number of hops allowed to reach the goal.
     * Precondition: dist > 0; numHops > 0
     */
    public FrogSimulation(int dist, int numHops)
    {
        goalDistance = dist;
        maxHops = numHops;
    }

    /** Returns an integer representing the distance, in inches, to be moved when the frog hops.
     */
    private int hopDistance()
    { /* implementation not shown */ }

    /** Simulates a frog attempting to reach the goal as described in part (a).
     * Returns true if the frog successfully reached or passed the goal during the simulation;
     * false otherwise.
     */
    public boolean simulate()
    { /* to be implemented in part (a) */ }

    /** Runs num simulations and returns the proportion of simulations in which the frog
     * successfully reached or passed the goal.
     * Precondition: num > 0
     */
    public double runSimulations(int num)
    { /* to be implemented in part (b) */ }
```

- (a) Write the `simulate` method, which simulates the frog attempting to hop in a straight line to a goal from the frog's starting position of 0 within a maximum number of hops. The method returns `true` if the frog successfully reached the goal within the maximum number of hops; otherwise, the method returns `false`.

The `FrogSimulation` class provides a method called `hopDistance` that returns an integer representing the distance (positive or negative) to be moved when the frog hops. A positive distance represents a move toward the goal. A negative distance represents a move away from the goal. The returned distance may vary from call to call. Each time the frog hops, its position is adjusted by the value returned by a call to the `hopDistance` method.

The frog hops until one of the following conditions becomes true:

- The frog has reached or passed the goal.
- The frog has reached a negative position.
- The frog has taken the maximum number of hops without reaching the goal.

The following example shows a declaration of a `FrogSimulation` object for which the goal distance is 24 inches and the maximum number of hops is 5. The table shows some possible outcomes of calling the `simulate` method.

```
FrogSimulation sim = new FrogSimulation(24, 5);
```

	Values returned by <code>hopDistance()</code>	Final position of frog	Return value of <code>sim.simulate()</code>
Example 1	5, 7, -2, 8, 6	24	true
Example 2	6, 7, 6, 6	25	true
Example 3	6, -6, 31	31	true
Example 4	4, 2, -8	-2	false
Example 5	5, 4, 2, 4, 3	18	false

Class information for this question

```
public class FrogSimulation

private int goalDistance
private int maxHops

private int hopDistance()
public boolean simulate()
public double runSimulations(int num)
```

Complete method `simulate` below. You must use `hopDistance` appropriately to receive full credit.

```
/** Simulates a frog attempting to reach the goal as described in part (a).
 * Returns true if the frog successfully reached or passed the goal during the simulation;
 * false otherwise.
```

- (b) Write the `runSimulations` method, which performs a given number of simulations and returns the proportion of simulations in which the frog successfully reached or passed the goal. For example, if the parameter passed to `runSimulations` is 400, and 100 of the 400 `simulate` method calls returned `true`, then the `runSimulations` method should return `0.25`.

Complete method `runSimulations` below. Assume that `simulate` works as specified, regardless of what you wrote in part (a). You must use `simulate` appropriately to receive full credit.

```
/** Runs num simulations and returns the proportion of simulations in which the frog
 * successfully reached or passed the goal.
 * @param num the number of simulations to run
 * @return the proportion of simulations in which the frog successfully reached or passed the goal
```

3. This question involves analyzing and modifying a string. The following `Phrase` class maintains a phrase in an instance variable and has methods that access and make changes to the phrase. You will write two methods of the `Phrase` class.

```
public class Phrase
{
    private String currentPhrase;

    /** Constructs a new Phrase object. */
    public Phrase(String p)
    { currentPhrase = p; }

    /** Returns the index of the nth occurrence of str in the current phrase;
     * returns -1 if the nth occurrence does not exist.
     * Precondition: str.length() > 0 and n > 0
     * Postcondition: the current phrase is not modified.
     */
    public int findNthOccurrence(String str, int n)
    { /* implementation not shown */ }

    /** Modifies the current phrase by replacing the nth occurrence of str with repl.
     * If the nth occurrence does not exist, the current phrase is unchanged.
     * Precondition: str.length() > 0 and n > 0
     */
    public void replaceNthOccurrence(String str, int n, String repl)
    { /* to be implemented in part (a) */ }

    /** Returns the index of the last occurrence of str in the current phrase;
     * returns -1 if str is not found.
     * Precondition: str.length() > 0
     * Postcondition: the current phrase is not modified.
     */
    public int findLastOccurrence(String str)
    { /* to be implemented in part (b) */ }

    /** Returns a string containing the current phrase. */
    public String toString()
    { return currentPhrase; }
}
```

Part (a) begins on page 12.

- (a) Write the `Phrase` method `replaceNthOccurrence`, which will replace the `nth` occurrence of the string `str` with the string `repl`. If the `nth` occurrence does not exist, `currentPhrase` remains unchanged.

Several examples of the behavior of the method `replaceNthOccurrence` are shown below.

Code segments

Output produced

<pre>Phrase phrase1 = new Phrase("A cat ate late."); phrase1.replaceNthOccurrence("at", 1, "rane"); System.out.println(phrase1);</pre>	A crane ate late.
--	-------------------

<pre>Phrase phrase2 = new Phrase("A cat ate late."); phrase2.replaceNthOccurrence("at", 6, "xx"); System.out.println(phrase2);</pre>	A cat ate late.
--	-----------------

<pre>Phrase phrase3 = new Phrase("A cat ate late."); phrase3.replaceNthOccurrence("bat", 2, "xx"); System.out.println(phrase3);</pre>	A cat ate late.
---	-----------------

<pre>Phrase phrase4 = new Phrase("aaaa"); phrase4.replaceNthOccurrence("aa", 1, "xx"); System.out.println(phrase4);</pre>	xxaa
---	------

<pre>Phrase phrase5 = new Phrase("aaaa"); phrase5.replaceNthOccurrence("aa", 2, "bbb"); System.out.println(phrase5);</pre>	abbba
--	-------

Class information for this question

```
public class Phrase
{
    private String currentPhrase
    public Phrase(String p)
    public int findNthOccurrence(String str, int n)
    public void replaceNthOccurrence(String str, int n, String repl)
    public int findLastOccurrence(String str)
    public String toString()
}
```

The `Phrase` class includes the method `findNthOccurrence`, which returns the `nth` occurrence of a given string. You must use `findNthOccurrence` appropriately to receive full credit.

Complete method `replaceNthOccurrence` below.

```
/** Modifies the current phrase by replacing the nth occurrence of str with repl.
 * If the nth occurrence does not exist, the current phrase is unchanged.
 * Precondition: str.length() > 0 and n > 0
 */
public void replaceNthOccurrence(String str, int n, String repl)
```

Part (b) begins on page 14.

- (b) Write the `Phrase` method `findLastOccurrence`. This method finds and returns the index of the last occurrence of a given string in `currentPhrase`. If the given string is not found, `-1` is returned. The following tables show several examples of the behavior of the method `findLastOccurrence`.

```
Phrase phrase1 = new Phrase("A cat ate late.");
```

Method call	Value returned
<code>phrase1.findLastOccurrence("at")</code>	11
<code>phrase1.findLastOccurrence("cat")</code>	2
<code>phrase1.findLastOccurrence("bat")</code>	-1

Class information for this question

```
public class Phrase
{
    private String currentPhrase
    public Phrase(String p)
    public int findNthOccurrence(String str, int n)
    public void replaceNthOccurrence(String str, int n, String repl)
    public int findLastOccurrence(String str)
    public String toString()
}
```

WRITE YOUR SOLUTION ON THE NEXT PAGE.

You must use `findNthOccurrence` appropriately to receive full credit.

Complete method `findLastOccurrence` below.

```
/** Returns the index of the last occurrence of str in the current phrase;
 * returns -1 if str is not found.
 * Precondition: str.length() > 0
 * Postcondition: the current phrase is not modified.
 */
```

2. This question involves reasoning about pairs of words that are represented by the following `WordPair` class.

```
public class WordPair
{
    /** Constructs a WordPair object. */
    public WordPair(String first, String second)
    { /* implementation not shown */ }

    /** Returns the first string of this WordPair object. */
    public String getFirst()
    { /* implementation not shown */ }

    /** Returns the second string of this WordPair object. */
    public String getSecond()
    { /* implementation not shown */ }
}
```

You will implement the constructor and another method for the following `WordPairList` class.

```
public class WordPairList
{
    /** The list of word pairs, initialized by the constructor. */
    private ArrayList<WordPair> allPairs;

    /** Constructs a WordPairList object as described in part (a).
     * Precondition: words.length >= 2
     */
    public WordPairList(String[] words)
    { /* to be implemented in part (a) */ }

    /** Returns the number of matches as described in part (b).
     */
    public int numMatches()
    { /* to be implemented in part (b) */ }
}
```

- (a) Write the constructor for the `WordPairList` class. The constructor takes an array of strings `words` as a parameter and initializes the instance variable `allPairs` to an `ArrayList` of `WordPair` objects.

A `WordPair` object consists of a word from the array paired with a word that appears later in the array. The `allPairs` list contains `WordPair` objects (`words[i]`, `words[j]`) for every `i` and `j`, where $0 \leq i < j < \text{words.length}$. Each `WordPair` object is added exactly once to the list.

The following examples illustrate two different `WordPairList` objects.

Example 1

```
String[] wordNums = {"one", "two", "three"};
WordPairList exampleOne = new WordPairList(wordNums);
```

After the code segment has executed, the `allPairs` instance variable of `exampleOne` will contain the following `WordPair` objects in some order.

```
("one", "two"), ("one", "three"), ("two", "three")
```

Example 2

```
String[] phrase = {"the", "more", "the", "merrier"};
WordPairList exampleTwo = new WordPairList(phrase);
```

After the code segment has executed, the `allPairs` instance variable of `exampleTwo` will contain the following `WordPair` objects in some order.

```
("the", "more"), ("the", "the"), ("the", "merrier"),
("more", "the"), ("more", "merrier"), ("the", "merrier")
```

Class information for this question

```
public class WordPair

public WordPair(String first, String second)
public String getFirst()
public String getSecond()

public class WordPairList

private ArrayList<WordPair> allPairs

public WordPairList(String[] words)
public int numMatches()
```

Complete the `WordPairList` constructor below.

```
/** Constructs a WordPairList object as described in part (a).
 * @param words words to be paired
 * @return a new WordPairList object
 */
```

- (b) Write the `WordPairList` method `numMatches`. This method returns the number of `WordPair` objects in `allPairs` for which the two strings match.

For example, the following code segment creates a `WordPairList` object.

```
String[] moreWords = {"the", "red", "fox", "the", "red"};
WordPairList exampleThree = new WordPairList(moreWords);
```

After the code segment has executed, the `allPairs` instance variable of `exampleThree` will contain the following `WordPair` objects in some order. The pairs in which the first string matches the second string are shaded for illustration.

```
("the", "red"), ("the", "fox"), ("the", "the"),
("the", "red"), ("red", "fox"), ("red", "the"),
("red", "red"), ("fox", "the"), ("fox", "red"),
("the", "red")
```

The call `exampleThree.numMatches()` should return 2.

Class information for this question

```
public class WordPair

public WordPair(String first, String second)
public String getFirst()
public String getSecond()

public class WordPairList

private ArrayList<WordPair> allPairs

public WordPairList(String[] words)
public int numMatches()
```

Complete method `numMatches` below.

```
/** Returns the number of matches as described in part (b).
 * @return the number of matches
 */
```

3 Writing a class – Part 1

Name: _____ Class: _____ Date: _____

Vocabulary 词汇

Write each word three times. 把每个单词抄写三遍。

English	中文	Write it 3 times (English)
class	类	_____
constructor	构造函数	_____

Recall

In earlier sheets you **used** objects like **String**. Now you will **build your own**:

- A **String** is one type of object; you can design your own types too.
- A class is like a blueprint for making objects.

This sheet lines up how to write a class. Each idea has a worked example.

New ideas

■ 1 A class is a blueprint

A **class** 类 is a blueprint that describes what its objects hold and do. From one class you make many objects.

■ 2 Fields

A class's **fields** are its data – the values each object stores:

```
public class Student {
    private String name;
    private int score;
}
```

■ 3 The constructor

A **constructor** 构造函数 sets up a new object when you use **new**:

```
public Student(String n, int s) {
    name = n;
    score = s;
}
```

■ 4 Making objects

```
Student a = new Student("Amy", 80);
```

Each **new** builds a separate object with its own **name** and **score**.

Watch out: a class is only a **blueprint** – it does nothing by itself. You must create an object with **new** before you can use it, just as a house plan is not a house.

Practice

Try these in order. The methods are all above.

2.1 State the difference between a class and an object. [2]

2.2 State what the “fields” of a class are. [1]

2.3 State what a constructor does. [2]

2.4 Write a line that creates a **Student** object called **b** with name “Ben” and score 70. [2]

2.5 Explain why you can make many different objects from one class.

[2]

Name: _____

AP Computer Science A: 2015

4. This question involves the design of an interface, writing a class that implements the interface, and writing a method that uses the interface.

- (a) A *number group* represents a group of integers defined in some way. It could be empty, or it could contain one or more integers.

Write an interface named `NumberGroup` that represents a group of integers. The interface should have a single `contains` method that determines if a given integer is in the group. For example, if `group1` is of type `NumberGroup`, and it contains only the two numbers `-5` and `3`, then `group1.contains(-5)` would return `true`, and `group1.contains(2)` would return `false`.

Write the complete `NumberGroup` interface. It must have exactly one method.

Part (b) begins on page 17.

- (b) A *range* represents a number group that contains all (and only) the integers between a minimum value and a maximum value, inclusive.

Write the `Range` class, which is a `NumberGroup`. The `Range` class represents the group of `int` values that range from a given minimum value up through a given maximum value, inclusive. For example, the declaration

```
NumberGroup range1 = new Range(-3, 2);
```

represents the group of integer values -3, -2, -1, 0, 1, 2.

Write the complete `Range` class. Include all necessary instance variables and methods as well as a constructor that takes two `int` parameters. The first parameter represents the minimum value, and the second parameter represents the maximum value of the range. You may assume that the minimum is less than or equal to the maximum.

Part (c) begins on page 18.

- (c) The `MultipleGroups` class (not shown) represents a collection of `NumberGroup` objects and is a `NumberGroup`. The `MultipleGroups` class stores the number groups in the instance variable `groupList` (shown below), which is initialized in the constructor.

```
private List<NumberGroup> groupList;
```

Write the `MultipleGroups` method `contains`. The method takes an integer and returns `true` if and only if the integer is contained in one or more of the number groups in `groupList`.

For example, suppose `multiple1` has been declared as an instance of `MultipleGroups` and consists of the three ranges created by the calls `new Range(5, 8)`, `new Range(10, 12)`, and `new Range(1, 6)`. The following table shows the results of several calls to `contains`.

Call	Result
<code>multiple1.contains(2)</code>	<code>true</code>
<code>multiple1.contains(9)</code>	<code>false</code>
<code>multiple1.contains(6)</code>	<code>true</code>

Complete method `contains` below.

```
/** Returns true if at least one of the number groups in this multiple group contains num;
 *     false otherwise.
 */
public boolean contains(int num)
```

STOP
END OF EXAM

3. The `StringChecker` interface describes classes that check if strings are valid, according to some criterion.

```
public interface StringChecker
{
    /** Returns true if str is valid. */
    boolean isValid(String str);
}
```

A `CodeWordChecker` is a `StringChecker`. A `CodeWordChecker` object can be constructed with three parameters: two integers and a string. The first two parameters specify the minimum and maximum code word lengths, respectively, and the third parameter specifies a string that must not occur in the code word. A `CodeWordChecker` object can also be constructed with a single parameter that specifies a string that must not occur in the code word; in this case the minimum and maximum lengths will default to 6 and 20, respectively.

The following examples illustrate the behavior of `CodeWordChecker` objects.

Example 1

```
StringChecker sc1 = new CodeWordChecker(5, 8, "$");
```

Valid code words have 5 to 8 characters and must not include the string "\$".

Method call	Return value	Explanation
<code>sc1.isValid("happy")</code>	true	The code word is valid.
<code>sc1.isValid("happy\$")</code>	false	The code word contains "\$".
<code>sc1.isValid("Code")</code>	false	The code word is too short.
<code>sc1.isValid("happyCode")</code>	false	The code word is too long.

Example 2

```
StringChecker sc2 = new CodeWordChecker("pass");
```

Valid code words must not include the string "pass". Because the bounds are not specified, the length bounds are 6 and 20, inclusive.

Method call	Return value	Explanation
<code>sc2.isValid("MyPass")</code>	true	The code word is valid.
<code>sc2.isValid("Mypassport")</code>	false	The code word contains "pass".
<code>sc2.isValid("happy")</code>	false	The code word is too short.
<code>sc2.isValid("1,000,000,000,000,000")</code>	false	The code word is too long.

Write the complete `CodeWordChecker` class. Your implementation must meet all specifications and conform to all examples.

3. The `StringChecker` interface describes classes that check if strings are valid, according to some criterion.

```
public interface StringChecker
{
    /** Returns true if str is valid. */
    boolean isValid(String str);
}
```

A `CodeWordChecker` is a `StringChecker`. A `CodeWordChecker` object can be constructed with three parameters: two integers and a string. The first two parameters specify the minimum and maximum code word lengths, respectively, and the third parameter specifies a string that must not occur in the code word. A `CodeWordChecker` object can also be constructed with a single parameter that specifies a string that must not occur in the code word; in this case the minimum and maximum lengths will default to 6 and 20, respectively.

The following examples illustrate the behavior of `CodeWordChecker` objects.

Example 1

```
StringChecker sc1 = new CodeWordChecker(5, 8, "$");
```

Valid code words have 5 to 8 characters and must not include the string `"$"`.

Method call	Return value	Explanation
<code>sc1.isValid("happy")</code>	<code>true</code>	The code word is valid.
<code>sc1.isValid("happy\$")</code>	<code>false</code>	The code word contains <code>"\$"</code> .
<code>sc1.isValid("Code")</code>	<code>false</code>	The code word is too short.
<code>sc1.isValid("happyCode")</code>	<code>false</code>	The code word is too long.

Example 2

```
StringChecker sc2 = new CodeWordChecker("pass");
```

Valid code words must not include the string `"pass"`. Because the bounds are not specified, the length bounds are 6 and 20, inclusive.

Method call	Return value	Explanation
<code>sc2.isValid("MyPass")</code>	<code>true</code>	The code word is valid.
<code>sc2.isValid("Mypassport")</code>	<code>false</code>	The code word contains <code>"pass"</code> .
<code>sc2.isValid("happy")</code>	<code>false</code>	The code word is too short.
<code>sc2.isValid("1,000,000,000,000,000")</code>	<code>false</code>	The code word is too long.

Write the complete `CodeWordChecker` class. Your implementation must meet all specifications and conform to all examples.

3 Scope, methods, and references — Part 2

Name: _____

Class: _____

Date: _____

Vocabulary 词汇

Write each word three times. 把每个单词抄写三遍。

English	中文	Write it 3 times (English)
Scope	作用域	_____

Recall

In Part A you built a class. Now two ideas about how variables and objects behave:

- A variable made inside a method only exists there.
- Passing an object into a method can change the original.

Each idea has a worked example before the Practice.

New ideas

■ 1 Scope

Scope 作用域 is where a name can be used. A variable declared inside a method (a **local** variable) exists **only** inside that method.

■ 2 Methods return values

A method can compute a value and **return** it:

```
public int doubleIt(int x) {  
    return x * 2;  
}
```

■ 3 Passing objects

When you pass an **object** to a method, Java passes a **reference** to it, so changes to its data are seen by the caller.

■ 4 Passing primitives

When you pass a **primitive** (like an **int**), Java passes a **copy**, so changing it inside the method does **not** affect the caller.

Watch out: changing an object's fields inside a method **does** affect the caller (it shares the object), but changing a copied **int** does **not**. Objects are shared; primitives are copied.

Practice

Try these in order. The methods are all above.

2.1 State what “scope” means. [1]

2.2 State where a local variable can be used. [1]

2.3 For `doubleIt` above, state what `doubleIt(6)` returns. [1]

2.4 State whether changing an object's field inside a method affects the caller, and why. [2]

2.5 State whether changing a passed `int` inside a method affects the caller, and why. [2]

2. This question involves the design of a class that will be used to produce practice problems. The following `StudyPractice` interface represents practice problems that can be used to study some subject.

```
public interface StudyPractice
{
    /** Returns the current practice problem. */
    String getProblem();

    /** Changes to the next practice problem. */
    void nextProblem();
}
```

The `MultiPractice` class is a `StudyPractice` that produces multiplication practice problems. A `MultiPractice` object is constructed with two integer values: *first integer* and *initial second integer*. The first integer is a value that remains constant and is used as the first integer in every practice problem. The initial second integer is used as the starting value for the second integer in the practice problems. This second value is incremented for each additional practice problem that is produced by the class.

For example, a `MultiPractice` object created with the call `new MultiPractice(7, 3)` would be used to create the practice problems "7 TIMES 3", "7 TIMES 4", "7 TIMES 5", and so on.

In the `MultiPractice` class, the `getProblem` method returns a string in the format of "*first integer* TIMES *second integer*". The `nextProblem` method updates the state of the `MultiPractice` object to represent the next practice problem.

The following examples illustrate the behavior of the `MultiPractice` class. Each table shows a code segment and the output that would be produced as the code is executed.

Example 1

Code segment	Output produced
<pre>StudyPractice p1 = new MultiPractice(7, 3); System.out.println(p1.getProblem());</pre>	7 TIMES 3
<pre>p1.nextProblem(); System.out.println(p1.getProblem());</pre>	7 TIMES 4
<pre>p1.nextProblem(); System.out.println(p1.getProblem());</pre>	7 TIMES 5
<pre>p1.nextProblem(); System.out.println(p1.getProblem());</pre>	7 TIMES 6

Example 2

Code segment	Output produced
<pre>StudyPractice p2 = new MultiPractice(4, 12); p2.nextProblem(); System.out.println(p2.getProblem()); System.out.println(p2.getProblem());</pre>	4 TIMES 13 4 TIMES 13
<pre>p2.nextProblem(); p2.nextProblem(); System.out.println(p2.getProblem());</pre>	4 TIMES 15
<pre>p2.nextProblem(); System.out.println(p2.getProblem());</pre>	4 TIMES 16

Question 2 continues on page 10.

Interface information for this question

public interface StudyPractice

```
String getProblem()
void nextProblem()
```

Write the complete `MultiPractice` class. Your implementation must be consistent with the specifications and the given examples.

2. The class `SingleTable` represents a table at a restaurant.

```
public class SingleTable
{
    /** Returns the number of seats at this table. The value is always greater than or equal to 4. */
    public int getNumSeats()
    { /* implementation not shown */ }

    /** Returns the height of this table in centimeters. */
    public int getHeight()
    { /* implementation not shown */ }

    /** Returns the quality of the view from this table. */
    public double getViewQuality()
    { /* implementation not shown */ }

    /** Sets the quality of the view from this table to value. */
    public void setViewQuality(double value)
    { /* implementation not shown */ }

    // There may be instance variables, constructors, and methods that are not shown.
}
```

At the restaurant, customers can sit at tables that are composed of two single tables pushed together. You will write a class `CombinedTable` to represent the result of combining two `SingleTable` objects, based on the following rules and the examples in the chart that follows.

- A `CombinedTable` can seat a number of customers that is two fewer than the total number of seats in its two `SingleTable` objects (to account for seats lost when the tables are pushed together).
- A `CombinedTable` has a desirability that depends on the views and heights of the two single tables. If the two single tables of a `CombinedTable` object are the same height, the desirability of the `CombinedTable` object is the average of the view qualities of the two single tables.
- If the two single tables of a `CombinedTable` object are not the same height, the desirability of the `CombinedTable` object is 10 units less than the average of the view qualities of the two single tables.

Assume `SingleTable` objects `t1`, `t2`, and `t3` have been created as follows.

- `SingleTable t1` has 4 seats, a view quality of 60.0, and a height of 74 centimeters.
- `SingleTable t2` has 8 seats, a view quality of 70.0, and a height of 74 centimeters.
- `SingleTable t3` has 12 seats, a view quality of 75.0, and a height of 76 centimeters.

The chart contains a sample code execution sequence and the corresponding results.

Statement	Value Returned (blank if no value)	Class Specification
<code>CombinedTable c1 = new CombinedTable(t1, t2);</code>		A <code>CombinedTable</code> is composed of two <code>SingleTable</code> objects.
<code>c1.canSeat(9);</code>	true	Since its two single tables have a total of 12 seats, <code>c1</code> can seat 10 or fewer people.
<code>c1.canSeat(11);</code>	false	<code>c1</code> cannot seat 11 people.
<code>c1.getDesirability();</code>	65.0	Because <code>c1</code> 's two single tables are the same height, its desirability is the average of 60.0 and 70.0.
<code>CombinedTable c2 = new CombinedTable(t2, t3);</code>		A <code>CombinedTable</code> is composed of two <code>SingleTable</code> objects.
<code>c2.canSeat(18);</code>	true	Since its two single tables have a total of 20 seats, <code>c2</code> can seat 18 or fewer people.
<code>c2.getDesirability();</code>	62.5	Because <code>c2</code> 's two single tables are not the same height, its desirability is 10 units less than the average of 70.0 and 75.0.
<code>t2.setViewQuality(80);</code>		Changing the view quality of one of the tables that makes up <code>c2</code> changes the desirability of <code>c2</code> , as illustrated in the next line of the chart. Since <code>setViewQuality</code> is a <code>SingleTable</code> method, you do not need to write it.
<code>c2.getDesirability();</code>	67.5	Because the view quality of <code>t2</code> changed, the desirability of <code>c2</code> has also changed.

The last line of the chart illustrates that when the characteristics of a `SingleTable` change, so do those of the `CombinedTable` that contains it.

Write the complete `CombinedTable` class. Your implementation must meet all specifications and conform to the examples shown in the preceding chart.

Begin your response at the top of a new page in the separate Free Response booklet and fill in the appropriate circle at the top of each page to indicate the question number. If there are multiple parts to this question, write the part letter with your response.

2. This question involves the implementation of a fitness tracking system that is represented by the `StepTracker` class. A `StepTracker` object is created with a parameter that defines the minimum number of steps that must be taken for a day to be considered *active*.

The `StepTracker` class provides a constructor and the following methods.

- `addDailySteps`, which accumulates information about steps, in readings taken once per day
- `activeDays`, which returns the number of active days
- `averageSteps`, which returns the average number of steps per day, calculated by dividing the total number of steps taken by the number of days tracked

The following table contains a sample code execution sequence and the corresponding results.

Statements and Expressions	Value Returned (blank if no value)	Comment
<code>StepTracker tr = new StepTracker(10000);</code>		Days with at least 10,000 steps are considered active. Assume that the parameter is positive.
<code>tr.activeDays();</code>	0	No data have been recorded yet.
<code>tr.averageSteps();</code>	0.0	When no step data have been recorded, the <code>averageSteps</code> method returns 0.0.
<code>tr.addDailySteps(9000);</code>		This is too few steps for the day to be considered active.
<code>tr.addDailySteps(5000);</code>		This is too few steps for the day to be considered active.
<code>tr.activeDays();</code>	0	No day had at least 10,000 steps.
<code>tr.averageSteps();</code>	7000.0	The average number of steps per day is (14000 / 2).
<code>tr.addDailySteps(13000);</code>		This represents an active day.
<code>tr.activeDays();</code>	1	Of the three days for which step data were entered, one day had at least 10,000 steps.
<code>tr.averageSteps();</code>	9000.0	The average number of steps per day is (27000 / 3).
<code>tr.addDailySteps(23000);</code>		This represents an active day.
<code>tr.addDailySteps(1111);</code>		This is too few steps for the day to be considered active.
<code>tr.activeDays();</code>	2	Of the five days for which step data were entered, two days had at least 10,000 steps.
<code>tr.averageSteps();</code>	10222.2	The average number of steps per day is (51111 / 5).

Write the complete `StepTracker` class, including the constructor and any required instance variables and methods. Your implementation must meet all specifications and conform to the example.

4 Arrays – Part 1

Name: _____ Class: _____ Date: _____

Vocabulary 词汇

Write each word three times. 把每个单词抄写三遍。

English	中文	Write it 3 times (English)
array	数组	_____

Recall

A single variable holds one value, but real problems have many:

- A class has many students' scores, not just one.
- You cannot make a separate variable for every value.

This sheet lines up how to store many values in an array. Each idea has a worked example.

New ideas

■ 1 What an array is

An **array** 数组 is a fixed-size, ordered list of values of the same type. Its positions are numbered from 0 to **length** - 1:

```
int[] vals = {3, 1, 4, 1, 5};
```

■ 2 Reading and writing

Use the index in square brackets:

```
int first = vals[0];    // 3
vals[1] = 9;           // change index 1 to 9
int n = vals.length;   // 5
```

■ 3 Looping through

Visit every element with a for loop:

```
for (int i = 0; i < vals.length; i++) {
    System.out.println(vals[i]);
}
```

■ 4 Common tasks

Summing or finding the largest is a loop with a running result.

Worked example. To sum {3, 1, 4}: start at 0, add each element → 0+3+1+4 = 8.

Watch out: the valid indices run from 0 to **length** - 1. For an array of length 5, **vals[5]** is **out of bounds** – the last valid index is 4.

Practice

Try these in order. The methods are all above. Use `int[] a = {7, 2, 9, 4};`.

2.1 State the value of **a[0]** and **a[2]**. [2]

2.2 State the value of **a.length**. [1]

2.3 State the largest valid index of **a**. [1]

2.4 Find the sum of all the elements of `a`.

[2]

2.5 State what is wrong with writing `a[4]`.

[2]

Name:

AP Computer Science A: 2021

3. A high school club maintains information about its members in a `MemberInfo` object. A `MemberInfo` object stores a club member's name, year of graduation, and whether or not the club member is in *good standing*. A member who is in good standing has fulfilled all the responsibilities of club membership.

A partial declaration of the `MemberInfo` class is shown below.

```
public class MemberInfo
{
    /** Constructs a MemberInfo object for the club member with name name,
     * graduation year gradYear, and standing hasGoodStanding.
     */
    public MemberInfo(String name, int gradYear, boolean hasGoodStanding)
    { /* implementation not shown */ }

    /** Returns the graduation year of the club member. */
    public int getGradYear()
    { /* implementation not shown */ }

    /** Returns true if the member is in good standing and false otherwise. */
    public boolean inGoodStanding()
    { /* implementation not shown */ }

    // There may be instance variables, constructors, and methods that are not shown.
}
```

The `ClubMembers` class maintains a list of current club members. The declaration of the `ClubMembers` class is shown below.

```
public class ClubMembers
{
    private ArrayList<MemberInfo> memberList;

    /** Adds new club members to memberList, as described in part (a).
     * Precondition: names is a non-empty array.
     */
    public void addMembers(String[] names, int gradYear)
    { /* to be implemented in part (a) */ }

    /** Removes members who have graduated and returns a list of members who have graduated
     * and are in good standing, as described in part (b).
     */
    public ArrayList<MemberInfo> removeMembers(int year)
    { /* to be implemented in part (b) */ }

    // There may be instance variables, constructors, and methods that are not shown.
}
```

- (a) Write the `ClubMembers` method `addMembers`, which takes two parameters. The first parameter is a `String` array containing the names of new club members to be added. The second parameter is the graduation year of all the new club members. The method adds the new members to the `memberList` instance variable. The names can be added in any order. All members added are initially in good standing and share the same graduation year, `gradYear`.

Complete the `addMembers` method.

```
/** Adds new club members to memberList, as described in part (a).
 * Precondition: names is a non-empty array.
 */
public void addMembers(String[] names, int gradYear)
```

Begin your response at the top of a new page in the separate Free Response booklet and fill in the appropriate circle at the top of each page to indicate the question number. If there are multiple parts to this question, write the part letter with your response.

- (b) Write the `ClubMembers` method `removeMembers`, which takes the following actions.
- Returns a list of all students who have graduated and are in good standing. A member has graduated if the member's graduation year is less than or equal to the method's `year` parameter. If no members meet these criteria, an empty list is returned.
 - Removes from `memberList` all members who have graduated, regardless of whether or not they are in good standing.

The following example illustrates the results of a call to `removeMembers`.

The `ArrayList` `memberList` before the method call `removeMembers(2018)`:

"SMITH, JANE"	"FOX, STEVE"	"XIN, MICHAEL"	"GARCIA, MARIA"
2019	2018	2017	2020
false	true	false	true

The `ArrayList` `memberList` after the method call `removeMembers(2018)`:

"SMITH, JANE"	"GARCIA, MARIA"
2019	2020
false	true

The `ArrayList` returned by the method call `removeMembers(2018)`:

"FOX, STEVE"
2018
true

Complete the `removeMembers` method.

```
/** Removes members who have graduated and returns a list of members who have graduated and are
 * in good standing, as described in part (b).
 */
public ArrayList<MemberInfo> removeMembers(int year)
```

Begin your response at the top of a new page in the separate Free Response booklet and fill in the appropriate circle at the top of each page to indicate the question number. If there are multiple parts to this question, write the part letter with your response.

Class information for this question

```
public class MemberInfo
```

```
public MemberInfo(String name, int gradYear, boolean hasGoodStanding)
public int getGradYear()
public boolean inGoodStanding()
```

```
public class ClubMembers
```

```
private ArrayList<MemberInfo> memberList
```

```
public void addMembers(String[] names, int gradYear)
public ArrayList<MemberInfo> removeMembers(int year)
```

COMPUTER SCIENCE A

SECTION II

Time—1 hour and 30 minutes

Number of questions—4

Percent of total score—50

Directions: SHOW ALL YOUR WORK. REMEMBER THAT PROGRAM SEGMENTS ARE TO BE WRITTEN IN JAVA.

Notes:

- Assume that the classes listed in the Java Quick Reference have been imported where appropriate.
- Unless otherwise noted in the question, assume that parameters in method calls are not `null` and that methods are called only when their preconditions are satisfied.
- In writing solutions for each question, you may use any of the accessible methods that are listed in classes defined in that question. Writing significant amounts of code that can be replaced by a call to one of these methods will not receive full credit.

1. This question involves the implementation and extension of a `RandomStringChooser` class.

- (a) A `RandomStringChooser` object is constructed from an array of non-null `String` values. When the object is first constructed, all of the strings are considered available. The `RandomStringChooser` class has a `getNext` method, which has the following behavior. A call to `getNext` returns a randomly chosen string from the available strings in the object. Once a particular string has been returned from a call to `getNext`, it is no longer available to be returned from subsequent calls to `getNext`. If no strings are available to be returned, `getNext` returns `"NONE"`.

The following code segment shows an example of the behavior of `RandomStringChooser`.

```
String[] wordArray = {"wheels", "on", "the", "bus"};
RandomStringChooser sChooser = new RandomStringChooser(wordArray);
for (int k = 0; k < 6; k++)
{
    System.out.print(sChooser.getNext() + " ");
}
```

One possible output is shown below. Because `sChooser` has only four strings, the string `"NONE"` is printed twice.

```
bus the wheels on NONE NONE
```

WRITE YOUR SOLUTION ON THE NEXT PAGE.

Write the entire `RandomStringChooser` class. Your implementation must include an appropriate constructor and any necessary methods. Any instance variables must be `private`. The code segment in the example above should have the indicated behavior (that is, it must compile and produce a result like the possible output shown). Neither the constructor nor any of the methods should alter the parameter passed to the constructor, but your implementation may copy the contents of the array.

Part (b) begins on page 4.

- (b) The following partially completed `RandomLetterChooser` class is a subclass of the `RandomStringChooser` class. You will write the constructor for the `RandomLetterChooser` class.

```
public class RandomLetterChooser extends RandomStringChooser
{
    /** Constructs a random letter chooser using the given string str.
     *   Precondition: str contains only letters.
     */
    public RandomLetterChooser(String str)
    { /* to be implemented in part (b) */ }

    /** Returns an array of single-letter strings.
     *   Each of these strings consists of a single letter from str. Element k
     *   of the returned array contains the single letter at position k of str.
     *   For example, getSingleLetters("cat") returns the
     *   array { "c", "a", "t" }.
     */
    public static String[] getSingleLetters(String str)
    { /* implementation not shown */ }
}
```

The following code segment shows an example of using `RandomLetterChooser`.

```
RandomLetterChooser letterChooser = new RandomLetterChooser("cat");
for (int k = 0; k < 4; k++)
{
    System.out.print(letterChooser.getNext());
}
```

The code segment will print the three letters in "cat" in one of the possible orders. Because there are only three letters in the original string, the code segment prints "NONE" the fourth time through the loop. One possible output is shown below.

actNONE

Assume that the `RandomStringChooser` class that you wrote in part (a) has been implemented correctly and that `getSingleLetters` works as specified. You must use `getSingleLetters` appropriately to receive full credit.

Complete the `RandomLetterChooser` constructor below.

```
/** Constructs a random letter chooser using the given string str.
 *   Precondition: str contains only letters.
 */
public RandomLetterChooser(String str)
```

2. This question involves reasoning about pairs of words that are represented by the following `WordPair` class.

```
public class WordPair
{
    /** Constructs a WordPair object. */
    public WordPair(String first, String second)
    { /* implementation not shown */ }

    /** Returns the first string of this WordPair object. */
    public String getFirst()
    { /* implementation not shown */ }

    /** Returns the second string of this WordPair object. */
    public String getSecond()
    { /* implementation not shown */ }
}
```

You will implement the constructor and another method for the following `WordPairList` class.

```
public class WordPairList
{
    /** The list of word pairs, initialized by the constructor. */
    private ArrayList<WordPair> allPairs;

    /** Constructs a WordPairList object as described in part (a).
     *   Precondition: words.length >= 2
     */
    public WordPairList(String[] words)
    { /* to be implemented in part (a) */ }

    /** Returns the number of matches as described in part (b).
     */
    public int numMatches()
    { /* to be implemented in part (b) */ }
}
```

- (a) Write the constructor for the `WordPairList` class. The constructor takes an array of strings `words` as a parameter and initializes the instance variable `allPairs` to an `ArrayList` of `WordPair` objects.

A `WordPair` object consists of a word from the array paired with a word that appears later in the array. The `allPairs` list contains `WordPair` objects (`words[i]`, `words[j]`) for every `i` and `j`, where $0 \leq i < j < \text{words.length}$. Each `WordPair` object is added exactly once to the list.

The following examples illustrate two different `WordPairList` objects.

Example 1

```
String[] wordNums = {"one", "two", "three"};
WordPairList exampleOne = new WordPairList(wordNums);
```

After the code segment has executed, the `allPairs` instance variable of `exampleOne` will contain the following `WordPair` objects in some order.

```
("one", "two"), ("one", "three"), ("two", "three")
```

Example 2

```
String[] phrase = {"the", "more", "the", "merrier"};
WordPairList exampleTwo = new WordPairList(phrase);
```

After the code segment has executed, the `allPairs` instance variable of `exampleTwo` will contain the following `WordPair` objects in some order.

```
("the", "more"), ("the", "the"), ("the", "merrier"),
("more", "the"), ("more", "merrier"), ("the", "merrier")
```

Class information for this question

```
public class WordPair
{
    public WordPair(String first, String second)
    public String getFirst()
    public String getSecond()

    public class WordPairList
    {
        private ArrayList<WordPair> allPairs

        public WordPairList(String[] words)
        public int numMatches()
    }
}
```

Complete the `WordPairList` constructor below.

```
/** Constructs a WordPairList object as described in part (a).
```

- (b) Write the `WordPairList` method `numMatches`. This method returns the number of `WordPair` objects in `allPairs` for which the two strings match.

For example, the following code segment creates a `WordPairList` object.

```
String[] moreWords = {"the", "red", "fox", "the", "red"};
WordPairList exampleThree = new WordPairList(moreWords);
```

After the code segment has executed, the `allPairs` instance variable of `exampleThree` will contain the following `WordPair` objects in some order. The pairs in which the first string matches the second string are shaded for illustration.

```
("the", "red"), ("the", "fox"), ("the", "the"),
("the", "red"), ("red", "fox"), ("red", "the"),
("red", "red"), ("fox", "the"), ("fox", "red"),
("the", "red")
```

The call `exampleThree.numMatches()` should return 2.

Class information for this question

```
public class WordPair
{
    public WordPair(String first, String second)
    public String getFirst()
    public String getSecond()
}

public class WordPairList
{
    private ArrayList<WordPair> allPairs

    public WordPairList(String[] words)
    public int numMatches()
}
```

Complete method `numMatches` below.

```
/** Returns the number of matches as described in part (b).
 * /
```

2. This question involves reasoning about pairs of words that are represented by the following `WordPair` class.

```
public class WordPair
{
    /** Constructs a WordPair object. */
    public WordPair(String first, String second)
    { /* implementation not shown */ }

    /** Returns the first string of this WordPair object. */
    public String getFirst()
    { /* implementation not shown */ }

    /** Returns the second string of this WordPair object. */
    public String getSecond()
    { /* implementation not shown */ }
}
```

You will implement the constructor and another method for the following `WordPairList` class.

```
public class WordPairList
{
    /** The list of word pairs, initialized by the constructor. */
    private ArrayList<WordPair> allPairs;

    /** Constructs a WordPairList object as described in part (a).
     *   Precondition: words.length >= 2
     */
    public WordPairList(String[] words)
    { /* to be implemented in part (a) */ }

    /** Returns the number of matches as described in part (b).
     */
    public int numMatches()
    { /* to be implemented in part (b) */ }
}
```

- (a) Write the constructor for the `WordPairList` class. The constructor takes an array of strings `words` as a parameter and initializes the instance variable `allPairs` to an `ArrayList` of `WordPair` objects.

A `WordPair` object consists of a word from the array paired with a word that appears later in the array. The `allPairs` list contains `WordPair` objects (`words[i]`, `words[j]`) for every `i` and `j`, where $0 \leq i < j < \text{words.length}$. Each `WordPair` object is added exactly once to the list.

The following examples illustrate two different `WordPairList` objects.

Example 1

```
String[] wordNums = {"one", "two", "three"};
WordPairList exampleOne = new WordPairList(wordNums);
```

After the code segment has executed, the `allPairs` instance variable of `exampleOne` will contain the following `WordPair` objects in some order.

```
("one", "two"), ("one", "three"), ("two", "three")
```

Example 2

```
String[] phrase = {"the", "more", "the", "merrier"};
WordPairList exampleTwo = new WordPairList(phrase);
```

After the code segment has executed, the `allPairs` instance variable of `exampleTwo` will contain the following `WordPair` objects in some order.

```
("the", "more"), ("the", "the"), ("the", "merrier"),
("more", "the"), ("more", "merrier"), ("the", "merrier")
```

Class information for this question

```
public class WordPair

public WordPair(String first, String second)
public String getFirst()
public String getSecond()

public class WordPairList

private ArrayList<WordPair> allPairs

public WordPairList(String[] words)
public int numMatches()
```

Complete the `WordPairList` constructor below.

```
/** Constructs a WordPairList object as described in part (a).
```

- (b) Write the `WordPairList` method `numMatches`. This method returns the number of `WordPair` objects in `allPairs` for which the two strings match.

For example, the following code segment creates a `WordPairList` object.

```
String[] moreWords = {"the", "red", "fox", "the", "red"};
WordPairList exampleThree = new WordPairList(moreWords);
```

After the code segment has executed, the `allPairs` instance variable of `exampleThree` will contain the following `WordPair` objects in some order. The pairs in which the first string matches the second string are shaded for illustration.

```
("the", "red"), ("the", "fox"), ("the", "the"),
("the", "red"), ("red", "fox"), ("red", "the"),
("red", "red"), ("fox", "the"), ("fox", "red"),
("the", "red")
```

The call `exampleThree.numMatches()` should return 2.

Class information for this question

```
public class WordPair

public WordPair(String first, String second)
public String getFirst()
public String getSecond()

public class WordPairList

private ArrayList<WordPair> allPairs

public WordPairList(String[] words)
public int numMatches()
```

Complete method `numMatches` below.

```
/** Returns the number of matches as described in part (b).
```

4 Searching and sorting – Part 2

Name: _____ Class: _____ Date: _____

Vocabulary 词汇

Write each word three times. 把每个单词抄写三遍。

English	中文	Write it 3 times (English)
Linear search	线性搜索	_____
Binary search	二分搜索	_____

Recall

In Part A you stored many values in an array. Now two everyday tasks:

- **Finding** a value in a list.
- **Sorting** a list into order.

Each idea has a worked example before the Practice.

New ideas

■ 1 Linear search

Linear search 线性搜索 checks each element in turn until it finds the target. It works on **any** list and takes up to n steps.

■ 2 Binary search

Binary search 二分搜索 works only on a **sorted** list: check the middle, then throw away the half that cannot contain the target, and repeat. Each step halves the list, so it takes about $\log_2 n$ steps.

Worked example. Search a sorted list of 8 items: $8 \rightarrow 4 \rightarrow 2 \rightarrow 1$, at most 3 comparisons – far fewer than checking all 8.

■ 3 Sorting

Sorting puts a list in order. Simple methods like **selection sort** repeatedly find the smallest remaining value and place it next.

■ 4 Why sorting helps

Once a list is sorted, binary search can find items much faster – which is why sorting is so useful.

Watch out: binary search only works on a **sorted** list. Running it on an unsorted list gives wrong answers – you must sort first.

Practice

Try these in order. The methods are all above.

2.1 State how linear search looks for a value. [1]

2.2 State the one thing binary search requires of the list. [1]

2.3 A sorted list has 16 items. State roughly the most comparisons binary search needs ($\log_2 16$). [2]

2.4 Explain why binary search is much faster than linear search on a large sorted list. [2]

2.5 State what would go wrong if you ran binary search on an unsorted list. [2]

4. This question involves reasoning about a number puzzle that is represented as a two-dimensional array of integers. Each element of the array initially contains a value between 1 and 9, inclusive. Solving the puzzle involves clearing pairs of array elements by setting them to 0. Two elements can be cleared if their values sum to 10 or if they have the same value. The puzzle is considered solved if all elements of the array are cleared.

You will write the constructor and one method of the `SumOrSameGame` class, which contains the methods that manipulate elements of the puzzle.

```
public class SumOrSameGame
{
    private int[][] puzzle;

    /**
     * Creates a two-dimensional array and fills it with random integers,
     * as described in part (a)
     * Precondition: numRows > 0; numCols > 0
     */
    public SumOrSameGame(int numRows, int numCols)
    { /* to be implemented in part (a) */ }

    /**
     * Identifies and clears an element of puzzle that can be paired with
     * the element at the given row and column, as described in part (b)
     * Preconditions: row and col are valid row and column indices in puzzle.
     * The element at the given row and column is between 1 and 9, inclusive.
     */
    public boolean clearPair(int row, int col)
    { /* to be implemented in part (b) */ }

    /* There may be instance variables, constructors,
       and methods that are not shown. */
}
```

- A.** Write the constructor for the `SumOrSameGame` class. The constructor initializes the instance variable `puzzle` to be a two-dimensional integer array with the number of rows and columns specified by the parameters `numRows` and `numCols`, respectively. Array elements are initialized with random integers between 1 and 9, inclusive, each with an equal chance of being assigned to each element of `puzzle`.

When an element of the two-dimensional array is accessed, the first index is used to specify the row and the second index is used to specify the column.

Complete the `SumOrSameGame` constructor.

```
/**
 * Creates a two-dimensional array and fills it with random integers,
 * as described in part (a)
 * Precondition: numRows > 0; numCols > 0
 */
public SumOrSameGame(int numRows, int numCols)
```

- B.** Write the `clearPair` method, which takes a valid row index and valid column index as its parameters. The array element specified by those indices, which has a value between 1 and 9, inclusive, is compared to other array elements in `puzzle` in an attempt to pair it with another array element that meets both of the following conditions.

- The row index of the second element is greater than or equal to the parameter `row`.
- The two elements have equal values or have values that sum to 10.

If such an array element is found, both array elements of the pair are cleared (set to 0) and the method returns `true`. If more than one such array element is found, any one of those identified array elements can be used to complete the pair and can be cleared. If no such array element is found, no changes are made to `puzzle` and the method returns `false`.

The following table shows the possible results of several calls to `clearPair`.

puzzle before call to <code>clearPair</code>	Method Call	puzzle after call to <code>clearPair</code>	Return Value	Explanation
0 7 9 0 7 4 1 6 8 4 1 8	<code>clearPair(0, 1)</code>	0 0 9 0 0 4 1 6 8 4 1 8	<code>true</code>	The value 7 in row 0, column 1 is matched with the value 7 in row 1, column 0.
1 2 3 4 5 6 7 8 5 4 1 2	<code>clearPair(2, 2)</code>	1 2 3 4 5 6 7 8 5 4 1 2	<code>false</code>	There is no element in row 2 or a later row to pair with the value 1.
8 1 0 5 0 4 3 6 3 4 5 8	<code>clearPair(1, 1)</code>	8 1 0 5 0 0 3 0 3 4 5 8	<code>true</code>	The value 4 in row 1, column 1 is matched with the value 6 in row 1, column 3. It could also have been matched with the value 4 in row 2, column 1.
1 7 9 2 6 5 4 4 4	<code>clearPair(0, 2)</code>	0 7 0 2 6 5 4 4 4	<code>true</code>	The value 9 in row 0, column 2 is matched with the value 1 in row 0, column 0.

Complete method `clearPair`.

```
/**
 * Identifies and clears an element of puzzle that can be paired with
 * the element at the given row and column, as described in part (b)
 * Preconditions: row and col are valid row and column indices in puzzle.
 * The element at the given row and column is between 1 and 9, inclusive.
 */
public boolean clearPair(int row, int col)
```

STOP
END OF EXAM

4. This question involves manipulating a two-dimensional array of integers. You will write two static methods of the `ArrayResizer` class, which is shown below.

```
public class ArrayResizer
{
    /** Returns true if and only if every value in row r of array2D is non-zero.
     * Precondition: r is a valid row index in array2D.
     * Postcondition: array2D is unchanged.
     */
    public static boolean isNonZeroRow(int[][] array2D, int r)
    { /* to be implemented in part (a) */ }

    /** Returns the number of rows in array2D that contain all non-zero values.
     * Postcondition: array2D is unchanged.
     */
    public static int numNonZeroRows(int[][] array2D)
    { /* implementation not shown */ }

    /** Returns a new, possibly smaller, two-dimensional array that contains only rows
     * from array2D with no zeros, as described in part (b).
     * Precondition: array2D contains at least one column and at least one row with no zeros.
     * Postcondition: array2D is unchanged.
     */
    public static int[][] resize(int[][] array2D)
    { /* to be implemented in part (b) */ }
}
```

- (a) Write the method `isNonZeroRow`, which returns `true` if and only if all elements in row `r` of a two-dimensional array `array2D` are not equal to zero.

For example, consider the following statement, which initializes a two-dimensional array.

```
int[][] arr = {{2, 1, 0},
              {1, 3, 2},
              {0, 0, 0},
              {4, 5, 6}};
```

Sample calls to `isNonZeroRow` are shown below.

Call to <code>isNonZeroRow</code>	Value Returned	Explanation
<code>ArrayResizer.isNonZeroRow(arr, 0)</code>	<code>false</code>	At least one value in row 0 is zero.
<code>ArrayResizer.isNonZeroRow(arr, 1)</code>	<code>true</code>	All values in row 1 are non-zero.
<code>ArrayResizer.isNonZeroRow(arr, 2)</code>	<code>false</code>	At least one value in row 2 is zero.
<code>ArrayResizer.isNonZeroRow(arr, 3)</code>	<code>true</code>	All values in row 3 are non-zero.

Complete the `isNonZeroRow` method.

```
/** Returns true if and only if every value in row r of array2D is non-zero.
 * Precondition: r is a valid row index in array2D.
 * Postcondition: array2D is unchanged.
 */
public static boolean isNonZeroRow(int[][] array2D, int r)
```

Begin your response at the top of a new page in the separate Free Response booklet and fill in the appropriate circle at the top of each page to indicate the question number. If there are multiple parts to this question, write the part letter with your response.

- (b) Write the method `resize`, which returns a new two-dimensional array containing only rows from `array2D` with all non-zero values. The elements in the new array should appear in the same order as the order in which they appeared in the original array.

The following code segment initializes a two-dimensional array and calls the `resize` method.

```
int[][] arr = {{2, 1, 0},
              {1, 3, 2},
              {0, 0, 0},
              {4, 5, 6}};
int[][] smaller = ArrayResizer.resize(arr);
```

When the code segment completes, the following will be the contents of `smaller`.

```
{{1, 3, 2}, {4, 5, 6}}
```

A helper method, `numNonZeroRows`, has been provided for you. The method returns the number of rows in its two-dimensional array parameter that contain no zero values.

Complete the `resize` method. Assume that `isNonZeroRow` works as specified, regardless of what you wrote in part (a). You must use `numNonZeroRows` and `isNonZeroRow` appropriately to receive full credit.

```
/** Returns a new, possibly smaller, two-dimensional array that contains only rows from array2D
 * with no zeros, as described in part (b).
 * Precondition: array2D contains at least one column and at least one row with no zeros.
 * Postcondition: array2D is unchanged.
 */
public static int[][] resize(int[][] array2D)
```

Begin your response at the top of a new page in the separate Free Response booklet and fill in the appropriate circle at the top of each page to indicate the question number. If there are multiple parts to this question, write the part letter with your response.

Class information for this question

```
public class ArrayResizer

public static boolean isNonZeroRow(int[][] array2D, int r)
public static int numNonZeroRows(int[][] array2D)
public static int[][] resize(int[][] array2D)
```

STOP

END OF EXAM

4. This question involves reasoning about a number puzzle that is represented as a two-dimensional array of integers. Each element of the array initially contains a value between 1 and 9, inclusive. Solving the puzzle involves clearing pairs of array elements by setting them to 0. Two elements can be cleared if their values sum to 10 or if they have the same value. The puzzle is considered solved if all elements of the array are cleared.

You will write the constructor and one method of the `SumOrSameGame` class, which contains the methods that manipulate elements of the puzzle.

```
public class SumOrSameGame
{
    private int[][] puzzle;

    /**
     * Creates a two-dimensional array and fills it with random integers,
     * as described in part (a)
     * Precondition: numRows > 0; numCols > 0
     */
    public SumOrSameGame(int numRows, int numCols)
    { /* to be implemented in part (a) */ }

    /**
     * Identifies and clears an element of puzzle that can be paired with
     * the element at the given row and column, as described in part (b)
     * Preconditions: row and col are valid row and column indices in puzzle.
     * The element at the given row and column is between 1 and 9, inclusive.
     */
    public boolean clearPair(int row, int col)
    { /* to be implemented in part (b) */ }

    /* There may be instance variables, constructors,
       and methods that are not shown. */
}
```

- A. Write the constructor for the `SumOrSameGame` class. The constructor initializes the instance variable `puzzle` to be a two-dimensional integer array with the number of rows and columns specified by the parameters `numRows` and `numCols`, respectively. Array elements are initialized with random integers between 1 and 9, inclusive, each with an equal chance of being assigned to each element of `puzzle`.

When an element of the two-dimensional array is accessed, the first index is used to specify the row and the second index is used to specify the column.

Complete the `SumOrSameGame` constructor.

```
/**
 * Creates a two-dimensional array and fills it with random integers,
 * as described in part (a)
 * Precondition: numRows > 0; numCols > 0
 */
public SumOrSameGame(int numRows, int numCols)
```

- B. Write the `clearPair` method, which takes a valid row index and valid column index as its parameters. The array element specified by those indices, which has a value between 1 and 9, inclusive, is compared to other array elements in `puzzle` in an attempt to pair it with another array element that meets both of the following conditions.

- The row index of the second element is greater than or equal to the parameter `row`.
- The two elements have equal values or have values that sum to 10.

If such an array element is found, both array elements of the pair are cleared (set to 0) and the method returns `true`. If more than one such array element is found, any one of those identified array elements can be used to complete the pair and can be cleared. If no such array element is found, no changes are made to `puzzle` and the method returns `false`.

The following table shows the possible results of several calls to `clearPair`.

puzzle before call to <code>clearPair</code>	Method Call	puzzle after call to <code>clearPair</code>	Return Value	Explanation
0 7 9 0 7 4 1 6 8 4 1 8	<code>clearPair(0, 1)</code>	0 0 9 0 0 4 1 6 8 4 1 8	<code>true</code>	The value 7 in row 0, column 1 is matched with the value 7 in row 1, column 0.
1 2 3 4 5 6 7 8 5 4 1 2	<code>clearPair(2, 2)</code>	1 2 3 4 5 6 7 8 5 4 1 2	<code>false</code>	There is no element in row 2 or a later row to pair with the value 1.
8 1 0 5 0 4 3 6 3 4 5 8	<code>clearPair(1, 1)</code>	8 1 0 5 0 0 3 0 3 4 5 8	<code>true</code>	The value 4 in row 1, column 1 is matched with the value 6 in row 1, column 3. It could also have been matched with the value 4 in row 2, column 1.
1 7 9 2 6 5 4 4 4	<code>clearPair(0, 2)</code>	0 7 0 2 6 5 4 4 4	<code>true</code>	The value 9 in row 0, column 2 is matched with the value 1 in row 0, column 0.

Complete method `clearPair`.

```
/**
 * Identifies and clears an element of puzzle that can be paired with
 * the element at the given row and column, as described in part (b)
 * Preconditions: row and col are valid row and column indices in puzzle.
 * The element at the given row and column is between 1 and 9, inclusive.
 */
public boolean clearPair(int row, int col)
```

STOP
END OF EXAM

4. This question involves reasoning about a number puzzle that is represented as a two-dimensional array of integers. Each element of the array initially contains a value between 1 and 9, inclusive. Solving the puzzle involves clearing pairs of array elements by setting them to 0. Two elements can be cleared if their values sum to 10 or if they have the same value. The puzzle is considered solved if all elements of the array are cleared.

You will write the constructor and one method of the `SumOrSameGame` class, which contains the methods that manipulate elements of the puzzle.

```
public class SumOrSameGame
{
    private int[][] puzzle;

    /**
     * Creates a two-dimensional array and fills it with random integers,
     * as described in part (a)
     * Precondition: numRows > 0; numCols > 0
     */
    public SumOrSameGame(int numRows, int numCols)
    { /* to be implemented in part (a) */ }

    /**
     * Identifies and clears an element of puzzle that can be paired with
     * the element at the given row and column, as described in part (b)
     * Preconditions: row and col are valid row and column indices in puzzle.
     * The element at the given row and column is between 1 and 9, inclusive.
     */
    public boolean clearPair(int row, int col)
    { /* to be implemented in part (b) */ }

    /* There may be instance variables, constructors,
       and methods that are not shown. */
}
```

- A. Write the constructor for the `SumOrSameGame` class. The constructor initializes the instance variable `puzzle` to be a two-dimensional integer array with the number of rows and columns specified by the parameters `numRows` and `numCols`, respectively. Array elements are initialized with random integers between 1 and 9, inclusive, each with an equal chance of being assigned to each element of `puzzle`.

When an element of the two-dimensional array is accessed, the first index is used to specify the row and the second index is used to specify the column.

Complete the `SumOrSameGame` constructor.

```
/**
 * Creates a two-dimensional array and fills it with random integers,
 * as described in part (a)
 * Precondition: numRows > 0; numCols > 0
 */
public SumOrSameGame(int numRows, int numCols)
```

- B. Write the `clearPair` method, which takes a valid row index and valid column index as its parameters. The array element specified by those indices, which has a value between 1 and 9, inclusive, is compared to other array elements in `puzzle` in an attempt to pair it with another array element that meets both of the following conditions.

- The row index of the second element is greater than or equal to the parameter `row`.
- The two elements have equal values or have values that sum to 10.

If such an array element is found, both array elements of the pair are cleared (set to 0) and the method returns `true`. If more than one such array element is found, any one of those identified array elements can be used to complete the pair and can be cleared. If no such array element is found, no changes are made to `puzzle` and the method returns `false`.

The following table shows the possible results of several calls to `clearPair`.

puzzle before call to <code>clearPair</code>	Method Call	puzzle after call to <code>clearPair</code>	Return Value	Explanation
0 7 9 0 7 4 1 6 8 4 1 8	<code>clearPair(0, 1)</code>	0 0 9 0 0 4 1 6 8 4 1 8	<code>true</code>	The value 7 in row 0, column 1 is matched with the value 7 in row 1, column 0.
1 2 3 4 5 6 7 8 5 4 1 2	<code>clearPair(2, 2)</code>	1 2 3 4 5 6 7 8 5 4 1 2	<code>false</code>	There is no element in row 2 or a later row to pair with the value 1.
8 1 0 5 0 4 3 6 3 4 5 8	<code>clearPair(1, 1)</code>	8 1 0 5 0 0 3 0 3 4 5 8	<code>true</code>	The value 4 in row 1, column 1 is matched with the value 6 in row 1, column 3. It could also have been matched with the value 4 in row 2, column 1.
1 7 9 2 6 5 4 4 4	<code>clearPair(0, 2)</code>	0 7 0 2 6 5 4 4 4	<code>true</code>	The value 9 in row 0, column 2 is matched with the value 1 in row 0, column 0.

Complete method `clearPair`.

```
/**
 * Identifies and clears an element of puzzle that can be paired with
 * the element at the given row and column, as described in part (b)
 * Preconditions: row and col are valid row and column indices in puzzle.
 * The element at the given row and column is between 1 and 9, inclusive.
 */
public boolean clearPair(int row, int col)
```
