3.3 Ratio analysis

Name: _____ Class: _____ Date: _____ **Total: 20 marks**

KEY WORDS gross profit margin • return on capital employed • current ratio • acid-test ratio • gearing • liquidity

Objective

Build the skills to answer exam questions on **ratio analysis** : profitability and liquidity ratios, and at HL efficiency ratios and gearing, and strategies to improve them.

You must be able to:

- calculate and interpret the gross profit margin, profit margin and ROCE
- calculate and interpret the current ratio and the acid-test ratio
- suggest strategies to improve profitability and liquidity

1 Key knowledge and worked examples

Ratio analysis

ratio	formula	what it shows
gross profit margin	$\frac{\text{gross profit}}{\text{sales revenue}} \times 100$	how well the firm controls direct costs and sets prices
profit margin	$\frac{\text{profit before interest and tax}}{\text{sales revenue}} \times 100$	how well it controls all its costs
return on capital employed (ROCE)	$\frac{\text{profit before interest and tax}}{\text{capital employed}} \times 100$	profit made on the money invested; capital employed = non-current liabilities + equity
current ratio	$\frac{\text{current assets}}{\text{current liabilities}}$	can it pay short-term debts? about 1.5–2 is often thought healthy
acid-test (quick) ratio	$\frac{\text{current assets} - \text{inventories}}{\text{current liabilities}}$	the same without stock, which may be hard to sell quickly; about 1 is often thought healthy

Improving profitability: raise prices (if demand is price-inelastic), find cheaper suppliers, cut waste and expenses, improve productivity, market higher-margin products. **Improving liquidity:** sell surplus stock, collect debts faster, delay payments to suppliers, sale and leaseback, a long-term loan to replace an overdraft.

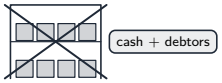

Ratios must be **compared**: with past years, with competitors, with the industry. Limits: they use past data, ignore non-financial factors, and depend on how the accounts were prepared.

- **inventory turnover** (times) $= \frac{\text{cost of sales}}{\text{average stock}}$, or in days $= \frac{\text{average stock}}{\text{cost of sales}} \times 365$;
- **debtor days** $= \frac{\text{trade receivables}}{\text{sales revenue}} \times 365$: how long customers take to pay;
- **creditor days** $= \frac{\text{trade payables}}{\text{cost of sales}} \times 365$: how long the firm takes to pay suppliers;
- **gearing** $= \frac{\text{non-current liabilities}}{\text{capital employed}} \times 100$: over 50% is usually high, so the firm is at risk if interest rates rise.

Answer shapes: formula → substitute → answer with units (%, : 1, days) → interpret against a benchmark → one strategy with a drawback.

2 Practice

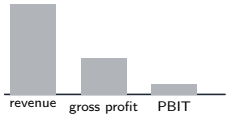

2.1 State the formula for the acid-test ratio, and explain why it leaves out inventories. [2]

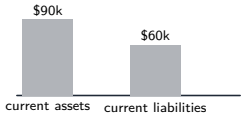

2.2 Distinguish between profitability and liquidity. [2]

2.3 A firm has sales revenue of $400,000, gross profit of $160,000 and profit before interest and tax of $48,000. Calculate its gross profit margin and its profit margin. [4]

2.4 A shop has current assets of \$90,000 and current liabilities of \$60,000. Calculate its current ratio and comment on the result. [2]

3 Exam-style questions

3.1 Nimbus Accessories sells phone cases and chargers. Its ratios for two years are shown. In year 2 it bought a large amount of stock of a new charger, which has sold slowly.

Using the data, discuss strategies Nimbus could use to improve its profitability and liquidity. [10]

ratio	year 1	year 2
gross profit margin	45%	38%
profit margin	15%	9%
current ratio	1.6	1.1
acid-test ratio	1.0	0.6
