

17.1 Electric fields: force and a positive test charge

Name: _____ Class: _____ Date: _____

Total: 10 marks

KEY WORDS test charge • electric field strength

Objective

Electric fields: force and a positive test charge. Supported HL concept preparation; original classroom practice, not an official IB paper or assessed learner work.

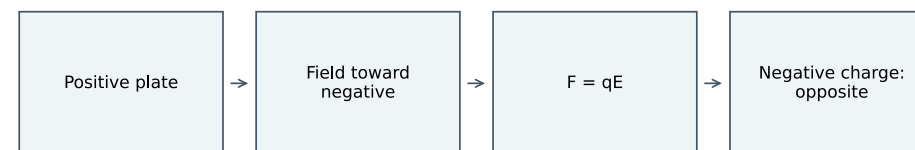

1 Key knowledge and worked examples

■ What would explain this observation?

- A negatively charged particle moves opposite to the direction of the electric field. Field direction is defined using a positive **test charge**.
- Start with a prediction. State the quantities or features you would compare, then decide what evidence could distinguish two explanations.

■ Build the model

- **Electric field strength** is force per unit positive test charge. Like charges repel and unlike charges attract. Field lines point away from positive charges and toward negative charges. Closely spaced lines represent a stronger field within a consistently drawn diagram.
- electric field strength: Electric force per unit positive test charge; test charge: A small charge used to probe an electric field.

■ Choose evidence that can test it

- In a uniform field between ideal parallel plates, $E = V/d$ away from edge effects. The force is $F = qE$, so its direction reverses for a negative charge. Coulomb force between ideal point charges decreases with separation squared.
- Sketch labelled plate polarities, field arrows and the charge before calculating. Convert separation to metres. In school, use simulations or approved low-voltage electrostatic models rather than exposed high-voltage equipment.

■ Work from known quantities

- State the known values and their units. Choose the relation because its assumptions fit this case, then rearrange before substitution.
- Known: plate potential difference is 120 V and separation is 0.020 m. $E = V/d = 6,000 \text{ V/m}$. A +2.0 microcoulomb charge experiences $F = qE = 0.012 \text{ N}$ along the field; a −2.0 microcoulomb charge experiences the same magnitude opposite to it.

Example:

Use $E = V/d$. Find E for 100 V across 0.025 m. Use the same sequence: known quantities → model → relation → substitution → unit and interpretation.

■ Check the conclusion and its limits

- Field strength is a vector. Potential difference is energy per charge and is not the same quantity. A field-line drawing is a model, not a set of physical threads.
- Return to the original observation. Explain what the result supports, which conditions it assumes, and one way to test a competing explanation.

Warn:

Every charged particle experiences a force along the electric field direction. This claim is false: Field strength is a vector. Potential difference is energy per charge and is not the same quantity. A field-line drawing is a model, not a set of physical threads.

Key:

Electric fields: force and a positive test charge: In a uniform field between ideal parallel plates, $E = V/d$ away from edge effects. The force is $F = qE$, so its direction reverses for a negative charge. Coulomb force between ideal point charges decreases with separation squared.

2 Practice

2.1 What happens to force direction if the test charge changes sign? Choose one answer.

- **A** It reverses in the same field
 - **B** It always stays along the field
 - **C** The field ceases to exist
- [1]

2.2 Use $E = V/d$. Find E for 100 V across 0.025 m. Show the relation, substitution and units.

[2]

2.3 Decide whether this claim is true and justify: Every charged particle experiences a force along the electric field direction.

[2]

2.4 Electric force per unit positive test charge: write the technical term.

[1]

3 Exam-style questions

3.1 Parallel plates have 120 V across 0.030 m. Find field and force on a -2.0 micro-coulomb charge. State directions and the uniform-field boundary.
