

E2.2 Algebraic manipulation

Name: _____ Class: _____ Date: _____

Total: 25 marks

KEY WORDS term 项 • expand 展开 • area 面积 • difference of two squares 平方差
• factorising 因式分解

Objective

Build the skills to answer Extended exam questions on **algebraic manipulation** 代数运算 — **expanding brackets** 展开括号 and **factorising** 因式分解 (common factors, difference of two squares, quadratics).

You must be able to:

- expand single and double brackets
- factorise by taking out a common factor
- factorise a difference of two squares and a quadratic

1 Worked examples

■ Expand and factorise

recognise $y = x^2$, $y = 1/x$, $y = 2^x$ from shape

Factorising is the reverse of expanding

- **Expand:** $(2x + 1)(x - 4) = 2x^2 - 7x - 4$.

$$3(x + 2) = 3x + 6$$

$a(b + c) = ab + ac$ · area model of expansion

The area model of expanding a bracket: $3(x + 2) = 3x + 6$

- **Common factor:** $9x^2 + 15xy = 3x(3x + 5y)$.
- **Difference of two squares** 平方差: $9x^2 - 16 = (3x + 4)(3x - 4)$.
- **Quadratic:** $2x^2 + 7x + 3 = (x + 3)(2x + 1)$ (split the middle term).

Answer shapes: M1 a correct method, A1 the correct answer.

■ Choosing the factorising method

Work through these in order; the first one that applies is the right one.

1. **Common factor first, every time.** $6x^2 + 9x = 3x(2x + 3)$. Missing it makes everything afterwards harder, and the mark for the common factor is lost even if the rest is right.
2. **Difference of two squares**, when there are two terms and both are squares with a minus between: $a^2 - b^2 = (a + b)(a - b)$. So $x^2 - 49 = (x + 7)(x - 7)$ and $9x^2 - 25 = (3x + 5)(3x - 5)$.
3. **A quadratic with $a = 1$:** find two numbers that multiply to the constant and add to the coefficient of x . For $x^2 + 3x - 10$ they are $+5$ and -2 , so it factorises as $(x + 5)(x - 2)$.
4. **A quadratic with $a \neq 1$:** multiply a by c , find two numbers multiplying to that and adding to b , split the middle term and factorise in pairs.
5. **Four terms:** factorise in pairs, then take out the common bracket: $xy + 2x + 3y + 6 = x(y + 2) + 3(y + 2) = (x + 3)(y + 2)$.

Worked example (the $a \neq 1$ method). Factorise $2x^2 + 5x - 3$.

1. $a \times c = 2 \times (-3) = -6$.
2. Two numbers multiplying to -6 and adding to $+5$: $+6$ and -1 .
3. Split the middle term: $2x^2 + 6x - x - 3$.

4. Factorise in pairs: $2x(x + 3) - 1(x + 3)$.
5. Take out the common bracket: $(2x - 1)(x + 3)$.

Always **check by expanding**. It takes one line and catches a sign error, which is the commonest loss on this topic.

2 Practice

2.1 Expand $3x(2x - 5)$. [1]

2.2 Factorise $6a + 9ab$. [1]

2.3 Expand and simplify $(x + 2)(x - 5)$. [2]

2.4 Factorise fully $12x^2 - 27$. [2]

2.5 Factorise $ab + 4a + 3b + 12$. [2]

3 Exam-style questions

3.1 Factorise $x^2 - 49$. [1]

3.2 Factorise $x^2 + 3x - 10$. [2]

3.3 Factorise $2x^2 + 5x - 3$. [2]

3.4 (a) Factorise fully $18x^2 - 8$. [3]

(b) Factorise $3x^2 - 11x + 6$. [3]

(c) Simplify $\frac{x^2 - 9}{x^2 + x - 12}$, showing your factorising. [3]

(d) Hence solve $\frac{x^2 - 9}{x^2 + x - 12} = 2$. [3]
